DECLARATION STATEMENT
for
RECORD OF DECISION
FORT RICHARDSON
ANCHORAGE, ALASKA
OPERABLE UNIT A AND OPERABLE UNIT B
AUGUST 1997

SOURCE AREA NAME AND LOCATION

Operable Unit A and Operable Unit B
Fort Richardson
Anchorage, Alaska

STATEMENT OF BASIS AND PURPOSE

This Record of Decision (ROD) presents the selected remedial actions for Operable Unit B (OU-B) and the rationale for addressing OU-A under a cleanup agreement with the State of Alaska at Fort Richardson. OU-A consists of three source areas: the Roosevelt Road Transmitter Site Leachfield (Transmitter Site); the Ruff Road Fire Training Area (Fire Training Area); and the Petroleum, Oil, and Lubricant Laboratory Dry Well (Dry Well). OU-B consists of one site: the Poleline Road Disposal Area (Poleline Road). This ROD was developed in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) as amended by the Superfund Amendments and Reauthorization Act of 1986; 42 United States Code 9601 et seq.; and, to the extent practicable, the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), 40 Code of Federal Regulations Part 300 et seq. This decision is based on the Administrative Record for both OUs.

The United States Army (Army); the United States Environmental Protection Agency (EPA); and the State of Alaska, through the Alaska Department of Environmental Conservation (ADEC), have agreed to the selected remedies.

ASSESSMENT OF THE SITE

Actual or threatened releases of hazardous substances from OU-B source areas, if not addressed by implementing the response actions selected in this ROD, may present an imminent or substantial threat to public health, public welfare, or the environment. OU-A is contaminated with petroleum compounds, and OU-B is contaminated with chlorinated solvents.

The OU-A and OU-B source areas are the first areas of Remedial Investigation to reach a final-action ROD at this National Priorities List site.

Final

August 8, 1997

DESCRIPTION OF THE SELECTED REMEDY

The Army, ADEC, and EPA have determined that the sources included within OU-A do not represent unacceptable risks to human health or the environment, based on EPA criteria. Thus, no remedial action is necessary to ensure protection of human health and the environment under CERCLA. However, the levels of petroleum contamination in the soil do exceed the ADEC soil cleanup criteria. Accordingly, these sites will be cleaned up under the State-Fort Richardson Environmental Restoration Agreement (Two-Party Agreement) in accordance with applicable State of Alaska regulations. The specific cleanup actions and the time required to remediate the source areas have yet to be determined. The components of the removal actions selected for OU-A will be detailed in separate decision documents prepared in accordance with the Two-Party Agreement.

A remedy was chosen from many alternatives as the best means of addressing contaminated soil and groundwater at OU-B. The selected remedy addresses the risk by reducing contamination to attain cleanup goals. The remedial action objectives for OU-B are designed to:

- Reduce contaminant levels in the groundwater to comply with drinking water standards;
- Prevent contaminated soil from continuing to act as a source of groundwater contamination;
- Prevent the contaminated groundwater from adversely affecting the Eagle River surface water and sediments; and
- Minimize degradation of the State of Alaska's groundwater resources at the site as a result of past disposal practices.

The major components of the preferred remedy for OU-B are:

- High-vacuum extraction (HVE) to remove contaminated vapors and groundwater from the "hot spot." The "hot spot" is defined as the subsurface area containing greater than 1.0 milligrams per liter of 1,1,2,2-tetrachloroethane in groundwater and/or free-phase solvents;
- An air stripping system to treat extracted groundwater to meet State of Alaska and federal maximum contaminant levels (MCLs) before being reinjected into the deep aquifer;
- Institutional controls that will include restrictions on groundwater well installations, site access restrictions, and maintenance of fencing until state and federal MCLs for drinking water are met;
- Natural attenuation of groundwater contamination in areas outside the "hot spot"; and

Final

August 8, 1997

- Long-term monitoring to assess whether groundwater contamination is approaching the Eagle River and to ensure that contamination levels in the groundwater are decreasing through natural attenuation.

Groundwater at Poleline Road is contaminated with volatile organic compounds, including chlorinated solvents. While there are no current uses of groundwater in the site area or seeps by which wildlife could be exposed to groundwater, modeling indicates that groundwater at the site eventually could reach the Eagle River. Modeling results indicated a time period of more than 100 years for on-site groundwater to reach the Eagle River.

Remediation of the site is necessary because the NCP Groundwater Protection Strategy requires consideration of current and potential future uses of groundwater in remedy selection, and protection and restoration of groundwater resources if necessary and practicable.

The selected remedy will be conducted in a multi-step approach because of the complexity of the contaminant characteristics and the hydrogeology of the site. The HVE system will be installed to reduce the quantity and concentration of contaminants in the "hot spot," and to prevent migration, to the maximum extent practicable, of contaminants above state and federal MCLs. Concurrently, technologies that could enhance the performance of the selected remedy will be evaluated in a Treatability Study, and if these enhancing technologies are deemed effective, they will be implemented to improve performance of the selected remedy. The plume outside the "hot spot" will be monitored to track plume migration and the progress of natural degradation processes. If cleanup of contaminants in the "hot spot" does not appear to be successful, then alternative remedial action goals and/or strategies will be pursued for the site (see Section 7.2).

STATUTORY DETERMINATION

The selected remedy is protective of human health and the environment, complies with federal and state requirements that are legally applicable or relevant and appropriate to the remedial action, and is cost-effective. The remedy utilizes permanent solutions and alternative treatment technologies to the maximum extent practicable, and satisfies the statutory preference for remedies that employ treatment that reduces toxicity, mobility, or volume as a principal element.

Because the remedy will result in hazardous substances remaining above regulatory levels on site, a review will be conducted within five years after commencement of the remedial action to ensure that the remedy continues to provide adequate protection of human health and the environment, and will continue for five-year increments until the remedy is complete.

DECISION SUMMARY**RECORD OF DECISION
for
OPERABLE UNITS A AND B
FORT RICHARDSON
ANCHORAGE, ALASKA
AUGUST 1997**

This Decision Summary provides an overview of the problems posed by the contaminants at Fort Richardson, Operable Unit A (OU-A) and OU-B source areas. This summary describes the physical features of the site, the contaminants present, and the associated risks to human health and the environment. The summary also describes the remedial alternatives considered at OU-B; provides the rationale for the remedial actions selected; and states how the remedial actions satisfy the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) statutory requirements.

The United States Army (Army) completed Remedial Investigations (RIs) for OU-A and OU-B to provide information regarding the nature and extent of contamination in the soils and groundwater. Baseline Human Health Risk Assessments (HHRAs) and Ecological Risk Assessments (ERAs) were developed and used in conjunction with the RIs to determine the need for remedial action and to aid in the selection of remedies. Feasibility Studies (FSs) were completed to evaluate remedial options.

Final

August 8, 1997

1.0 SITE DESCRIPTIONS

Fort Richardson, established in 1940 as a military staging and supply center during World War II, originally occupied 162,000 acres north of Anchorage. In 1950, the Fort was divided between the Army and the Air Force. The Fort now occupies approximately 56,000 acres bounded to the west by Elmendorf Air Force Base, to the east by Chugach State Park, and to the north and south by the Municipality of Anchorage (see Figure 1-1).

Fort Richardson's land use supports its current mission to provide the services, facilities, and infrastructure necessary to support the rapid deployment of Army forces from Alaska to the Pacific Theater. The area managed by Elmendorf adjacent to Fort Richardson is dedicated to military and recreational use.

The Post contains features that include flat to rolling wooded terrain. The upland areas near the adjacent Chugach Mountain Range rise to approximately 5,000 feet above mean sea level. The Post is located in a climatic transition zone between the maritime climate of the coast and the continental interior climate of Alaska.

The predominant vegetation type at Fort Richardson comprises varying-aged stands of mixed coniferous and deciduous forest. The diverse plant communities provide habitats for a diverse wildlife population including moose, bear, Dall sheep, swans, and waterfowl. There are no known threatened or endangered species residing on the Post.

Five major Pleistocene glaciations have shaped the Cook Inlet basin. These glacial deposits become thicker as they progress from the Chugach Mountain Range to Cook Inlet. Remnants of the glaciation include the massive Elmendorf Moraine, alluvial fans, and a large outwash deposit called the *Naptowne Outwash*. The Elmendorf Moraine comprises poorly sorted, unconsolidated till with boulders, gravel, sand, and silt. The moraine acts as a surface water divide, but not as a groundwater divide.

Two major aquifers exist in the Anchorage area; they dip westward and extend from the Chugach Mountain Range across the Anchorage basin (see Figure 1-2). Most groundwater flows in the Naptowne and Knik glacial outwash sands and gravels. Relatively little groundwater flows in the underlying consolidated bedrock of the Kenai Formation because of the bedrock's low permeability. Well logs from previous investigations indicate that wells installed in bedrock yield small quantities of water.

The Naptowne and Knik outwash aquifers are replenished by surface water runoff from the mountains, direct infiltration of precipitation, and percolation from surface waters. Groundwater flows through these deposits into glacial outwash sediments beneath portions of Fort Richardson south of the Elmendorf Moraine.

Fort Richardson obtains drinking water from the Ship Creek Dam Reservoir and has several emergency supply wells near Ship Creek. Groundwater used for the emergency water supply is obtained from the confined aquifer in the Knik outwash deposit. Water storage for Fort Richardson is

Final

August 8, 1997

provided by a permanent 2.5-million-gallon underground reservoir in the Elmendorf Moraine, and by the Ship Creek Dam Reservoir at the base of the Chugach Mountain Range. A water treatment plant near the dam processes the drinking water.

Fort Richardson has generated and disposed of various hazardous substances since it began operations. The Fort was added to the United States Environmental Protection Agency's (EPA's) National Priorities List (NPL) in June 1994. On December 5, 1994, the Army, Alaska Department of Environmental Conservation (ADEC), and EPA signed a Federal Facility Agreement (FFA) that outlines the procedures and schedules required for a thorough investigation of suspected historical hazardous substance sources at Fort Richardson. The FFA divided Fort Richardson into four OUs: OU-A, OU-B, OU-C, and OU-D. Only OU-A and OU-B are addressed in this Record of Decision (ROD; see Figure 1-1). OU-C and OU-D will be addressed in future RODs. The potential source areas were grouped into OUs based on the amount of existing information and the similarity of potential hazardous substance contamination.

1.1 OPERABLE UNIT A

OU-A comprises three source areas: the Roosevelt Road Transmitter Site Leachfield (Transmitter Site); the Ruff Road Fire Training Area (Fire Training Area); and the Building 986 Petroleum, Oil, and Lubricant (POL) Laboratory Dry Well (Dry Well).

1.1.1 Site Locations and Description

The Transmitter Site is located north of the main Fort area near Otter Lake; the site is illustrated in Figure 1-3. The site includes an underground communications bunker used from World War II through the Korean War. The sanitary facilities within the bunker are connected to a septic leachfield that was the subject of the OU-A RI.

The Fire Training Area is located east of Bryant Airfield near the Glenn Highway (see Figure 1-4). The site consists of an area used for fire-fighting exercises from the 1940s to 1980. The exercises involved applying fuels and other waste combustible liquids to an unlined earthen pit, igniting the fuels, and extinguishing the resulting fires with water.

The Dry Well is located at Building 986 within the main cantonment area of Fort Richardson, near Loop Road and Warehouse Street (see Figure 1-5). The Dry Well opening is approximately 4 feet in diameter, with a concrete collar and a metal and plywood cover. The Dry Well was used for the disposal of drain and sink water from the adjacent POL laboratory. Numerous chemicals were used at the POL laboratory during performance of quality testing of fuels used at Fort Richardson.

1.1.2 Land Use

While land use at the Transmitter Site and Fire Training Area is generally recreational, the Dry Well is a working laboratory. In the future, continued recreational land use (i.e., hiking, hunting, etc.) at the Transmitter Site and Fire Training Area represents the most likely scenario. Continued industrial use of the Dry Well area is expected in the future.

Final

August 8, 1997

1.2 OPERABLE UNIT B

1.2.1 Site Location and Description

OU-B consists of one site: the Poleline Road Disposal Area (Poleline Road). Poleline Road is located in the north portion of Fort Richardson, approximately 1 mile south of the Eagle River and 0.6 mile north of the Anchorage Regional Landfill (see Figure 1-6). The site is situated in a low-lying wooded area at Poleline Road and Barrs Boulevard. The site was used as a chemical disposal area from 1950 to 1972. During this time, chemical agent identification sets and other military debris were burned and disposed of in trenches. The chemical sets were neutralized with a mixture of bleach or lime and chlorinated solvents before burial.

1.2.2 Hydrogeology and Groundwater Use

Four water-bearing intervals have been identified at Poleline Road: a perched zone, a shallow groundwater zone, an intermediate groundwater zone, and a deep aquifer (see Figure 1-7). The saturated intervals are separated by zones of very dense, low-porosity, compact tills, and the detection of contaminants in all four intervals suggest that they are interconnected to some degree. The top of the perched interval was encountered at 4 feet to 10 feet below ground surface (BGS) and is approximately 5 feet thick. The shallow saturated zone is an average of 10 feet thick; the top was encountered at 20 feet to 25 feet BGS. Groundwater in the shallow zone flows in a northeasterly direction (see Figure 1-6). The intermediate zone was encountered at approximately 65 feet to 95 feet BGS. The deep aquifer is an advance moraine/till complex with a thickness between 3 feet and 40 feet and was encountered at 80 feet to 125 feet BGS. Groundwater elevations indicate that the flow direction in the deep aquifer is locally to the northeast and regionally to the northwest (see Figure 1-6). Hydraulic conductivities were estimated from existing site data and averaged 0.5 feet per day (ft/day) for all saturated zones, except that the intermediate zone averaged 0.05 ft/day. These relatively low hydraulic conductivities suggest that groundwater flow in the site area would not significantly disperse dissolved contaminants.

Available data indicate that the deep aquifer below Poleline Road is not connected with the aquifers used for drinking water in the community of Eagle River (more than 1 mile to the northeast). It is unlikely that groundwater beneath Poleline Road ever would be used for a drinking water supply. Yield from the intermediate, shallow, and perched saturated zones would be too low to supply an average household, and the installation of septic systems would preclude use of the shallow or perched zones for drinking water. The deep aquifer may provide sufficient yield, but the installation of drinking water wells in the deep aquifer is unlikely based on the present growth pattern in the area.

1.2.3 Land Use

The Army uses the land surrounding Poleline Road for military training activities and recreational purposes. OU-B is situated on public domain land that belongs to the United States Department of Interior, Bureau of Land Management. This land is withdrawn from the public domain for military purposes. U.S. Army Alaska holds no deed documents for this land.

2.0 SITE HISTORIES AND ENFORCEMENT ACTIVITIES

2.1 SITE HISTORIES BEFORE REMEDIAL INVESTIGATIONS

2.1.1 Site History of Operable Unit A

2.1.1.1 Roosevelt Road Transmitter Site Leachfield

The Transmitter Site was utilized from World War II through the end of the Korean War as part of the Alaska Communications System, established to provide command and control communications in the event of enemy attacks on Anchorage or Fort Richardson. The leachfield was associated with the sanitary system facilities at the underground bunker. Two sewer lines originate from the west side of the bunker and extend westward, eventually connecting to a septic tank and a concrete cesspool that is the nucleus of the leachfield. The quantity of sewage disposed of through the septic system is unknown. Additionally, at least two other sewage disposal facilities were present at the Transmitter Site.

During 1978, vandalism of several transformers stored in the former transmitter annex building resulted in a spill of dielectric oils containing polychlorinated biphenyls (PCBs). The spill later was remediated by washing the concrete foundation of the former transmitter annex building with diesel fuel. The date of this action is not documented in existing records; however, anecdotal information suggests that the washing action occurred in 1979. In 1988, 150 tons of PCB-contaminated soil surrounding the concrete pad was excavated. Another cleanup effort was conducted in 1992, when at least 600 tons of PCB-contaminated soil was removed.

Three separate investigations were performed at the site between 1988 and 1990 to determine the presence and extent of PCB contamination inside and around the underground bunker. As part of the 1990 investigation, two samples and a duplicate were collected from the leachfield cesspool. The sampling records indicate that the material sampled was sludge and soil. Analytical results of these samples showed the presence of volatile organic compounds (VOCs) and semi-VOCs, PCBs, and heavy metals. Because of the limited amount of sludge-like material observed in the cesspool during the RI, most of this contaminated material may have been removed from the cesspool through sample collection during the 1990 investigation. Alternatively, the cesspool identified during the 1990 investigation may have been the septic tank that could not be located during the RI and that is believed to have been excavated and removed during soil removal operations at the site in 1992.

2.1.1.2 Ruff Road Fire Training Area

The Fire Training Area began operations during the initial establishment of the Post in approximately 1940, and it was used until 1980 to conduct exercises for training fire department and rescue crews. The fire training exercises were conducted by saturating unlined excavations with water, pumping fuel into the excavations, and igniting the fuel. Petroleum fuel products burned during the fire training exercises included jet fuel, waste oil, diesel, brake fluid, and solvents. Based on the assumption that 1,500 gallons to 2,300 gallons of combustible material was burned annually at this site, approximately 85,500 gallons of wastes was burned and disposed of at the Fire Training Area.

Final

August 8, 1997

The former Fire Training Area has been estimated to be an area of petroleum-stained soils approximately 50 feet in diameter. In 1991, the original road in the area was demolished and the present Ruff Road was constructed. The charred debris associated with the Fire Training Area was removed at that time. In 1994, the Fire Training Area was filled with approximately 18 inches of soil and regraded. During winter 1994, the National Guard parked vehicles at the present site. No visual evidence of the Fire Training Area remains.

Three investigations were conducted at the Fire Training Area—in 1986, 1989, and from 1991 to 1992—to determine the presence and extent of contamination at the site and to estimate potential human health and environmental risks. Analytical results from these investigations documented the presence of petroleum hydrocarbons; benzene, toluene, ethylbenzene, and total xylenes; and dioxins in surface and subsurface soils at the site.

Conclusions from the most recent investigation during 1991 to 1992 suggested that concentrations of petroleum and dioxin were high enough to warrant remediation. The highest levels of contamination were detected in the surface and near-surface soils in the immediate area of the fire training pit. This area later was regraded, and much of the original surface soil was spread and/or buried beneath up to 3 feet of fill.

2.1.1.3 Petroleum, Oil, and Lubricant Laboratory Dry Well

The Dry Well has been used from the 1950s to the present, but the quantity of waste discharged to the Dry Well from the laboratory has not been documented. Operations performed at the POL laboratory include analysis of various fuels such as motor gas, aviation fuel, JP-4, and arctic-grade diesel for United States Government quality assurance purposes.

An 800-gallon underground storage tank was located north of Building 986 until 1992. The tank received the same laboratory waste as the Dry Well. The Army drilled eight soil borings around the tank in 1991 as part of the removal effort. Several soil samples collected from the borings indicated the presence of petroleum hydrocarbons at 10 feet to 20 feet BGS. Following removal of the tank in 1992, the tank excavation was sampled and backfilled with clean fill and closed in accordance with the cleanup standards set forth by the State of Alaska.

The Army conducted an investigation at the Dry Well in November 1992 to determine the presence and extent of contaminants in the well. During the investigation, approximately 18 inches of water and 6 inches to 8 inches of sludge were observed in the well at approximately 15 feet BGS. Analytical results indicated that the sludge and water contained petroleum hydrocarbons and heavy metals, including arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver.

2.1.2 Site History of Operable Unit B

Poleline Road was identified in 1990 through interviews conducted by the Army with two former soldiers who were stationed at Fort Richardson in the 1950s and who recalled the disposal of chemicals, smoke bombs, and Japanese cluster bombs. The disposal location was corroborated by a 1954 United States Army Corps of Engineers map showing a "Chemical Disposal Area" at Poleline

Final

August 8, 1997

Road and by 1957 aerial photography showing trenches in the area. The disposal area was active from approximately 1950 to 1972.

The site was divided further into four disposal areas: Areas A-1, A-2, A-3, and A-4. Areas A-3 and A-4 showed the greatest evidence of buried waste and trenching. Historical information describes how relatively shallow (8-foot- to 10-foot-deep) trenches were dug and used for the disposal of a wide variety of debris, including chemical agent training kits. During this time, a layer of "bleach/lime" was laid in the bottom of the trench, and then the materials contaminated with chemical weapons were placed on a pallet in the trench. Diesel fuel was poured on the agent and then ignited with thermal grenades. After burning was complete, a mixture of either bleach or lime, combined with chlorinated solvent carrier (trichloroethene [TCE]; tetrachloroethene [PCE]; and 1,1,2,2-tetrachloroethane), was poured over the materials to neutralize the chemical agent.

During the 1993 and 1994 removal action, contaminated debris and soil were removed from Areas A-3 and A-4. Included during this removal action were individual components of gas identification sets that were issued by the Army Chemical Warfare Service during the 1940s and 1950s. These sets were used to train military personnel in the identification of chemical warfare agents. Among the training set components were their drawn steel cylindrical shipping containers, also referred to as *pigs*. Of the approximately 12 pigs recovered at the site, seven were intact and moved to a secure storage location on Fort Richardson. The pigs will be analyzed to verify their contents and will be opened. Their contents will be neutralized by Army chemical destruction personnel. This action is scheduled for late Fiscal Year 1998.

Soils were excavated to a maximum depth of 14 feet, where groundwater was encountered. During the removals, sampling indicated the presence of chlorinated solvents, including TCE; PCE; and 1,1,2,2-tetrachloroethane, in soil and groundwater within 20 feet of the surface. Removal action concentration levels were established for TCE (600 milligrams per kilogram [mg/kg]); PCE (100 mg/kg); and 1,1,2,2-tetrachloroethane (30 mg/kg). Soils that exceeded these action levels were stockpiled in lined, plastic-covered piles surrounded by berms on Barrs Boulevard southeast of the site. The stockpile area is fenced, and remediation of the stockpiled soil from the removal action is scheduled to begin in 1997. A geophysical survey was performed in 1995 to determine whether any suspicious material remained in the recently excavated areas. Results of the survey indicated that the burial material had been removed.

Sampling was not conducted at Areas A-1 and A-2 because of the potential presence of unexploded ordnance. However, geophysical surveys of these areas indicate that they contain lesser quantities of buried waste than Areas A-3 and A-4. In addition, sampling of soil and groundwater surrounding Areas A-1 and A-2 did not detect any compounds or breakdown products associated with ordnance. The sampling did detect relatively lower concentrations of chlorinated solvents than levels detected near Areas A-3 and A-4.

2.2 ENFORCEMENT ACTIVITIES

Fort Richardson was placed on the CERCLA NPL in June 1994. Consequently, an FFA was signed in December 1994 by EPA, ADEC, and the United States Department of Army. The FFA details the

Final

August 8, 1997

responsibilities and authority associated with each party pursuant to the CERCLA process and the environmental investigation and remediation requirements associated with Fort Richardson. The FFA divided Fort Richardson into four OUs, two of which are OU-A and OU-B, and outlines the general requirements for investigation and/or remediation of suspected historical hazardous waste source areas associated with Fort Richardson.

2.3 HIGHLIGHTS OF COMMUNITY PARTICIPATION

The public was encouraged to participate in the selection of the remedies for OU-A and OU-B during a public comment period from January 20 to February 18, 1997. The *Fort Richardson Proposed Plan for Remedial Action, Operable Units A and B* presents combinations of options considered by the Army, EPA, and ADEC to address contamination in soil and groundwater. The Proposed Plan was released to the public on January 17, 1997, and was sent to 150 known interested parties, including elected officials and concerned citizens.

The Proposed Plan summarizes available information regarding OU-A and OU-B. Additional materials were placed in information repositories established at the Alaska Resources Library, Fort Richardson Post Library, and University of Alaska Anchorage Consortium Library. An Administrative Record, including other documents used in the selection of the remedial actions, was established in the Public Works Environmental Resource Office on Fort Richardson. The public is welcome to inspect materials available in the Administrative Record and the information repositories during business hours. The Administrative Record Index is provided in Appendix A.

Interested citizens were invited to comment on the Proposed Plan and the remedy selection process by mailing comments to the Fort Richardson project manager; by calling a toll-free telephone number to record a comment; or by attending and commenting at a public meeting on January 29, 1997, at the Russian Jack Chalet in Anchorage. Fifteen people attended the public meeting. Two comments were received from the public during the comment period.

The Responsiveness Summary in Appendix B provides more details regarding community relations activities and summarizes and addresses public comments on the Proposed Plan and the remedy selection process.

2.4 SCOPE AND ROLE OF OPERABLE UNITS

The OU-A and OU-B RI/FSs were performed in accordance with the RI/FS Management Plans for OU-A and OU-B, respectively. The RI fieldwork for both OUs was conducted during summer 1995.

The principal contamination at source areas within OU-A is petroleum in soil but does not pose unacceptable risks to human health. Because the levels of contamination exceed ADEC soil cleanup criteria, the Agencies (U.S. Army Alaska, EPA, and ADEC) have elected to pursue further cleanup efforts at these sites under the State-Fort Richardson Environmental Restoration Agreement (Two-Party Agreement). Decisions regarding specific cleanup alternatives for OU-A source areas will be documented in separate decision documents, and cleanup will be conducted in accordance with applicable State of Alaska regulations.

Final

August 8, 1997

The principal contamination at OU-B is chlorinated solvents in soil and groundwater. Based on the origin and nature of disposal, these chlorinated solvents are not listed hazardous wastes under the Resource Conservation and Recovery Act (RCRA). According to results of the RI, potential risks to human health and the environment are posed by on-site contamination. Accordingly, the Agencies have elected to pursue remedial actions under Superfund to address these potential risks.

Final

August 8, 1997

3.0 SUMMARY OF SITE CHARACTERISTICS

Physical features, hydrogeologic conditions, and the nature and extent of contamination for OU-A and OU-B are described briefly in the following sections.

3.1 OPERABLE UNIT A

3.1.1 Physical Features, Hydrogeologic Conditions, and Transport Pathways

The northern and central sections of Fort Richardson, where the OU-A source areas are located, feature flat to gently rolling, wooded terrain, including ponds and numerous streams leading from the mountains and uplands westward to Cook Inlet. Drainages flow mainly west-northwest into the Knik Arm. However, streams in the southernmost portion of the Fort, including Ship Creek, flow through Anchorage before entering the Knik Arm.

3.1.1.1 Roosevelt Road Transmitter Site Leachfield

The Transmitter Site is located near the northern margin of the Elmendorf Moraine on the Naptowne Outwash deposits. Site soil boring logs indicate that the soil consists of dry, massive, very dense, well-graded gravel and sand, with minor silt and clay.

The Transmitter Site is located in an undeveloped portion of Fort Richardson. The site is surrounded by forests. Wetlands are located within 0.5 mile of the site to the southwest, southeast, and northeast.

Groundwater at the Transmitter Site occurs from 88 feet to 99 feet BGS (approximately 176 feet to 178 feet above mean sea level [AMSL]) within a sandy gravel deposit of the Naptowne Outwash Formation. Groundwater generally flows southwest with an estimated gradient of 0.01. This groundwater flow direction is not consistent with the regional west-northwest groundwater flow.

Because the contaminant source is in the subsurface, the most likely contaminant migration pathway at the Transmitter Site is lateral and vertical transport through subsurface soil. Groundwater is not a contaminant migration pathway, as indicated by the absence of contaminants in the samples collected at the site. Figure 3-1 presents a conceptual site model (CSM) based on the results of the RI.

3.1.1.2 Ruff Road Fire Training Area

The Fire Training Area is located near the southern margin of the Elmendorf Moraine on the Naptowne Outwash deposits. Site soil boring logs indicate that the soil consists of dry, massive, well-graded gravel, with minor silt and clay.

The Fire Training Area is located within an area used for gravel excavation and is surrounded by relatively undisturbed forested areas. A wetland is located approximately 600 feet from the southwest corner of the former Fire Training Area. A former gravel pit is located approximately 0.6 mile south and hydraulically upgradient of the site. The pit has filled with water, which is likely an expression

Final

August 8, 1997

of a localized, perched groundwater zone.

Groundwater occurs from 140 feet to 153 feet BGS (approximately 236 feet to 250 feet AMSL) and within the unconfined sandy gravel to gravelly sand aquifer. Groundwater generally flows westward and has an average horizontal hydraulic gradient from 0.018 to 0.023. These conditions are consistent with the regional hydrogeologic characteristics described in Section 1.2.2.

Contaminants were detected in surface and subsurface soil. Off-site contaminant transport through surface runoff and windblown particulates is possible but not expected to contribute significantly to contaminant transport from the site. The absence of site-related contaminants in the surface water and sediment samples collected at the nearby pond substantiates the conclusion that surface water runoff and particulate transport are not migration pathways of concern at the Fire Training Area. The RI conducted transport modeling of petroleum constituents in the subsurface soils. The model predicted that petroleum contaminants will migrate approximately 10 feet vertically from their present location over a 90-year period and that groundwater likely would not be impacted. Based on this result and the absence of contaminants in groundwater samples collected at the site, groundwater is not a contaminant migration pathway. Figure 3-2 presents a CSM based on the results of the RI.

3.1.1.3 Petroleum, Oil, and Lubricant Laboratory Dry Well

The Dry Well is located near the southern margin of the Elmendorf Moraine on the Naptowne Outwash deposits. Soil boring logs indicate that the soil consists of dry, massive, very dense, well-graded gravel and sand, with minor silt and clay.

The Dry Well is located in a partially developed portion of the Fort Richardson main installation. Patches of developed/disturbed forests surround the site. No known wetlands occur within a 0.5-mile radius of Building 986.

The Dry Well was completed to a depth of 18 feet. Groundwater occurs mainly within a silty sand bed of the Naptowne Outwash Formation from 113 feet to 122 feet BGS (approximately 177 feet to 181 feet AMSL). Groundwater generally flows west with an average gradient from 0.001 to 0.006. These conditions are consistent with the regional hydrogeologic characteristics described in Section 1.2.2.

Contaminants were detected in sludge and subsurface soil. The sludge and the Dry Well will be removed during the upcoming field season. Lateral and vertical migration of contaminants through subsurface soil is the most important pathway at the site. Based on results obtained during the RI, lateral contaminant migration has been restricted to an area within an approximately 40-foot radius of the Dry Well. Contaminant transport modeling suggests that petroleum contaminants would migrate approximately 11 feet vertically from their present location during a 90-year period. Because the distance between the deepest soil contamination at the Dry Well and the groundwater table is approximately 40 feet, the likelihood of groundwater contamination caused by contaminants leached from subsurface soil is low. Based on the results of the RI, neither volatilization of contaminants to air nor particulate transport of contaminants by wind is a release mechanism. Figure 3-3 presents a CSM for the Dry Well.

Final

August 8, 1997

3.1.2 Nature and Extent of Contamination

3.1.2.1 Roosevelt Road Transmitter Site Leachfield

In 1990, a limited characterization of the septic system was performed. A cesspool sample was obtained from a layer of sludge and detritus on the bottom of the concrete-lined cesspool, while soil samples were obtained from sloughed material in the cesspool. Analytical results indicated the presence of VOCs, base/neutral and acid extractable organic compounds (BNAs), PCBs (up to 5,600 micrograms per kilogram [$\mu\text{g/kg}$]), and heavy metals including copper (up to 1,100 mg/kg) and lead (up to 1,200 mg/kg). During the 1990 investigation, analysis for fuel was not performed.

The OU-A RI was conducted in 1995. The principal objectives of the RI were to conduct a geophysical survey and to investigate the cesspool, subsurface soil, and groundwater. The results of the RI indicated that soils in isolated locations within the leachfield have been impacted by petroleum contamination. Table 3-1 provides the locations and concentrations of site-related contaminants in subsurface soils. Low levels of heavy metals and PCBs were encountered. The presence of diesel-range organics (DRO) in subsurface soils indicates that these contaminants have dispersed from the leachfield and associated plumbing and have migrated to 15 feet BGS. The lateral extent of DRO contamination appears to be limited to an area extending northwest from the buried sewer line, which connects the transmitter building and the cesspool, to a portion of the leachfield. The presence of PCBs near the bunker at 5 feet BGS suggests that either contaminated soil was reworked during remedial activities or that limited migration through subsurface soils has occurred. These concentrations probably represent residual contamination remaining from remedial activities conducted between 1988 and 1992 at the transmitter annex foundation. Therefore, it is unlikely that this contamination is related to discharges from the leachfield or its associated plumbing.

Sloughed soils within the cesspool contained petroleum hydrocarbons; PCB Aroclor 1260; cyanide; and heavy metals including barium, cadmium, lead, and mercury (see Table 3-2). Petroleum hydrocarbons were detected up to a maximum concentration of 23,000 mg/kg. Cyanide was detected at a concentration of 1.2 mg/kg.

No site-related contaminants were detected at concentrations exceeding state and federal maximum contaminant levels (MCLs) in the Transmitter Site groundwater samples.

3.1.2.2 Ruff Road Fire Training Area

Previous investigations were conducted at the Fire Training Area in 1986, in 1989, and from 1991 to 1992.

In 1986, the Army drilled three soil borings and collected 20 subsurface soil samples at the site. Eight samples were analyzed for VOCs, but VOCs were not detected at concentrations exceeding detection limits.

In 1989, as part of the Installation Restoration Program, 15 soil-gas probes were installed in the area to a depth of 9 feet. Benzene, toluene, and xylene were identified in the soil-gas samples with

Final

August 8, 1997

maximum concentrations of 250 parts per million (ppm), 2,500 ppm, and 1,200 ppm, respectively.

In 1991, the Army collected surface and subsurface soil samples at the site. A composite surface soil sample was collected in triplicate from stained soil near the center of the Fire Training Area. The sample contained lead (80.8 ppm to 543 ppm), diesel and other fuels (10,000 ppm to 20,000 ppm), pyrene (750 $\mu\text{g/kg}$), PCE (48 $\mu\text{g/kg}$ to 485 $\mu\text{g/kg}$), toluene (732 $\mu\text{g/kg}$), xylene (1,116 $\mu\text{g/kg}$), bis(2-ethylhexyl)phthalate (4,100 $\mu\text{g/kg}$), and dioxins (0.0022 $\mu\text{g/kg}$ toxicity equivalency factor). Subsurface soil samples also were collected during the 1991 effort. The highest VOC concentrations detected in these samples were acetone (283 $\mu\text{g/kg}$), TCE (46 $\mu\text{g/kg}$), toluene (56 $\mu\text{g/kg}$), and xylene (42 $\mu\text{g/kg}$). The investigation was continued in 1992. Analytical results obtained in 1992 confirmed the presence of petroleum contamination in surface and subsurface soils. Dioxins also were detected in the surface soils; one sample contained a maximum concentration of 45.4 $\mu\text{g/kg}$ dioxin toxicity equivalency factor.

The RI field investigation was conducted in 1995 to further investigate surface and subsurface soils, groundwater, and surface water/sediment. As mentioned in Section 2.1.1.2 (page 12), the site was covered with approximately 18 inches of soil and regraded in 1994. Accordingly, the RI samples were collected from the current soil surface (fill) and the former soil surface that was characterized in the 1991 to 1992 investigation. The results confirmed the presence of petroleum hydrocarbons and dioxins in the surface and subsurface soil. Maximum contaminant concentrations detected in the RI soil samples include 3,400 mg/kg DRO, 1,300 mg/kg gasoline-range organics, 5,400 mg/kg total recoverable petroleum hydrocarbons, and 0.0239 $\mu\text{g/kg}$ dioxin toxicity equivalency factor (see Figure 3-4). VOCs, semivolatile organic compounds (SVOCs), and lead concentrations detected during the RI were significantly lower than the 1991 to 1992 results. None of the RI soil samples contained dioxin concentrations within three orders of magnitude of the 1992 soil results, which indicates that the maximum 1992 result was associated with a very localized "hot spot" or was related to an analytical error.

The lateral extent of surface soil contamination was estimated based on the findings of the RI and previous site investigations, and by applying ADEC's *Interim Guidance for Non-UST Contaminated Soil Cleanup Levels* for petroleum hydrocarbons. Contamination above the acceptable cleanup level is estimated conservatively to be confined to an area 175 feet by 190 feet. Figure 3-5 depicts the approximate boundaries of lateral contamination. No contamination was detected in any of the subsurface soil samples collected from depths greater than 5 feet BGS. Using these boundaries, the estimated volume of contaminated soil is 6,200 cubic yards. Tables 3-3 and 3-4 summarize the frequency of detection, range, and locations of maximum concentrations of analytes detected in surface and subsurface soil.

No site-related contaminants were detected in groundwater and surface water/sediment samples. Inorganic elements were detected in these samples, but the concentration levels were consistent with naturally occurring background levels.

3.1.2.3 Petroleum, Oil, and Lubricant Laboratory Dry Well

The Army conducted an investigation at the Dry Well in November 1992 to determine the presence

Final

August 8, 1997

and extent of contaminants in the well. During the investigation, approximately 18 inches of water and 6 inches to 8 inches of sludge were observed in the well at approximately 15 feet BGS. The sludge contained VOCs; BNAs; petroleum hydrocarbons; and heavy metals including arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver. Table 3-5 summarizes the analytes detected during the 1992 investigation.

Sludge samples collected from the bottom of the Dry Well during the RI field investigation showed concentrations of petroleum hydrocarbons as kerosene (67,000 mg/kg); cyanide (6.8 mg/kg); and heavy metals including barium, chromium, lead, silver, and mercury (see Table 3-6). The results of the RI indicated that this sludge is contaminated with petroleum products and that approximately 230 cubic yards of petroleum-contaminated subsurface soil is near the bottom of the Dry Well. The heavy metals chromium and mercury also were detected in subsurface soil at the site (see Table 3-7). VOCs were not encountered in soil at levels expected to pose a risk to human health or the environment. The petroleum constituents detected in subsurface soils exceed Alaska cleanup levels for petroleum-contaminated soils; however, the other contaminants of concern (COCs) detected in soil do not exceed EPA's Region 3 risk-based concentrations (RBCs).

Groundwater has not been impacted by petroleum-contaminated sludge and subsurface soil at the site. However, high levels of chloroform, methylene chloride, and manganese were detected. Chloroform and methylene chloride are laboratory contaminants associated with the sample analysis performed for this site; moreover, neither chloroform nor methylene chloride was detected in sludge or subsurface soil samples collected at the Dry Well, which makes it unlikely that chloroform and methylene chloride are contaminating groundwater. Based on results of previous investigations, the presence of manganese in the groundwater samples is likely attributable to naturally occurring minerals in groundwater at the site.

3.2 OPERABLE UNIT B

3.2.1 Physical Features, Hydrogeologic Conditions, and Transport Pathways

Poleline Road is a low-lying, relatively flat area bordered by wooded hills to the northwest and southeast. Wetlands are located directly south and southwest of disposal Areas A-1 and A-4 (see Figure 1-6). The remaining area bordering Poleline Road is relatively flat and wooded.

The surficial deposits of the region are fluvially reworked glacial sediments and glacial tills. These deposits appear to be up to 30 feet thick at the site and consist of unstratified to poorly stratified clays, silts, sands, gravels, and boulders. A basal till lies below the surficial deposits and overlies an advance moraine/till complex. Underlying the glacial sediments is bedrock composed of a hard black fissile claystone.

The subsurface soils collected during the 1995 field investigation were glacial tills, generally described as silty sands with some gravel. The soils at Poleline Road were difficult to drill through and sample because of the high density.

The hydrogeologic conditions are discussed in Section 1.2.2. Dissolved contaminants in groundwater

Final

August 8, 1997

will migrate through advective forces, influenced by horizontal and vertical groundwater flow gradients.

3.2.2 Nature and Extent of Contamination

In 1993 and 1994, contaminated debris and soil were removed from two of four burial locations. Soils were excavated to a maximum depth of 14 feet, where groundwater was encountered. During the removals, sampling indicated the presence of chlorinated solvents. Solvents found in soil during this removal included TCE at a maximum concentration of 360 mg/kg; PCE at a maximum concentration of 25 mg/kg; and 1,1,2,2-tetrachloroethane at a maximum concentration of 2,920 mg/kg. During the 1993 removal action, the site was divided into four areas corresponding to the four disposal areas identified previously: Areas A-1, A-2, A-3, and A-4 (see Figure 1-6). Another geophysical survey was performed in 1995 and indicated that the buried material had been removed.

Areas A-1 and A-2 have not been excavated or sampled because of the potential presence of unexploded ordnance. Additionally, there are no breakdown products from the unexploded ordnance, which suggests that Areas A-1 and A-2 do not appear to be an ongoing source of groundwater contamination. Lesser contaminant concentrations were detected in the soils and groundwater surrounding Areas A-1 and A-2. The groundwater flow pattern suggests that the contaminants detected near groundwater zones in Areas A-1 and A-2 migrated there from Areas A-3 and A-4. Contaminants detected during surface sampling near Area A-2 were due to migration from Areas A-3 and A-4.

During the RI, the highest concentrations of contaminants detected in soil and groundwater samples were found in Areas A-3 and A-4 (see Tables 3-8, 3-9, and 3-10). This area of greatest contamination at the site is referred to as the "hot spot" and encompasses an area approximately 150 feet by 300 feet that is bounded by a 1 milligram per liter (mg/L; 1,000 micrograms per liter [$\mu\text{g/L}$]) or greater concentration of 1,1,2,2-tetrachloroethane in groundwater (see Figure 3-6). The highest soil concentrations of these contaminants were encountered more than 15 feet BGS at the "hot spot." The results of the RI indicated the presence of chlorinated solvents in soil up to a maximum concentration of 2,030 mg/kg for 1,1,2,2-tetrachloroethene. PCE; TCE; and 1,1,2,2-tetrachloroethane in contaminated soils are a continuing source of groundwater contamination.

The RI results also indicated the presence of four main water-bearing zones underneath the site (see Table 3-10). Chlorinated solvent contamination, including TCE and 1,1,2,2-tetrachloroethene, was detected in all four groundwater zones. TCE concentrations exceeded the state and federal MCL of 5 $\mu\text{g/L}$ in the perched, shallow, and deep aquifers. 1,1,2,2-Tetrachloroethane was detected up to a maximum concentration of 1,900 mg/L in the perched groundwater zone. While 1,1,2,2-tetrachloroethane does not have a state or federal MCL, its RBC (tap water), based on an excess cancer risk of 1×10^{-4} , is 0.052 mg/L. This concentration was exceeded in the perched, shallow, and deep water-bearing zones. Studies performed at the site indicated that the contaminated groundwater in the deep aquifer is flowing regionally northwest toward the Eagle River, but in the immediate vicinity of Poleline Road it is flowing to the northeast (see Figure 3-6); groundwater flow modeling results suggested that this contaminated groundwater could migrate to the Eagle River within 120 years.

Final

August 8, 1997

During fall 1996, a Treatability Study was conducted at the site to evaluate the effectiveness of potential remedial technologies addressed in the FS. The Treatability Study involved field tests to evaluate the potential performance of soil vapor extraction (SVE) and air sparging (AS) of groundwater. The studies also involved characterization of hydraulic conductivity of water-bearing zones underlying the site and collection of groundwater samples to assess which types of natural attenuation processes may be degrading contaminants in groundwater. The study concluded that SVE may reduce contamination at the site but AS would not be an effective technology to remediate contaminants in groundwater. The study also concluded that biological components of natural attenuation would not be an important degradation mechanism. However, other attenuation processes, such as adsorption and dispersion, are expected to decrease contaminant concentrations over time.

Groundwater sampling to determine dissolved oxygen levels during the study revealed a two-phase sample of groundwater in the sampling bailer. This was the first time that such a sample was observed at the site, and it was not observed during a single follow-up sampling event to characterize the separate phases at the same location. The two-phase sample was drawn from a newly installed 2-inch-diameter polyvinyl chloride well, screened between 28 feet and 33 feet BGS in the shallow groundwater interval. This well is located several feet from MW-14, which was the location of the highest groundwater contaminant concentrations at OU-B during the RI. MW-14 is screened at approximately 15 feet BGS in the perched groundwater interval.

<p align="center">Table 3-1</p> <p align="center">SUMMARY OF RI SUBSURFACE SOIL SAMPLES EXCEEDING SCREENING CRITERIA</p> <p align="center">ROOSEVELT ROAD TRANSMITTER SITE LEACHFIELD</p> <p align="center">OPERABLE UNIT A</p> <p align="center">FORT RICHARDSON, ALASKA</p> <p align="center">(mg/kg, except as noted)</p>

Final

August 8, 1997

4.0 SUMMARY OF SITE RISKS

Baseline Risk Assessments were conducted to determine the necessity for and extent of remediation to be protective of human health and the environment. The detailed reports discussing this evaluation are *Risk Assessment Report, Operable Unit A* and *Risk Assessment Report, Operable Unit B* and are available at the information repositories. The risk evaluations were based on the location and amount of contamination, toxicity of each contaminant, current and potential future land use by each site, and pathways by which people could be exposed to contaminants. The Risk Assessment results were used to support decisions concerning the extent of remediation and to aid in the selection of remedial technologies.

The estimated risks from each pathway are added to determine total risk. The potential for adverse effects to human health is evaluated for carcinogens and noncarcinogens. The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) defines the acceptable risk range at Superfund sites as excess lifetime cancer risks ranging from 1 in 10,000 (1×10^{-4}) to 1 in 1 million (1×10^{-6}). This means that an individual could face up to a 1 in 10,000 to 1 in 1 million chance of developing cancer because of exposure to chemicals at a site, beyond those cancers expected from other causes. Noncarcinogenic effects are evaluated by calculating the ratio between the estimated intake of a contaminant and its corresponding reference dose (RfD); that is, the intake level at which no adverse health effects are expected to occur. This ratio is a summation of all site contaminants. If this ratio, called a *hazard index (HI)*, is less than 1, then noncarcinogenic health effects are not expected at the site.

4.1 OPERABLE UNIT A

The sites within OU-A are used for industrial or recreational purposes. No residential areas are located within a 1-mile radius of these sites. The Post does not use groundwater as a source for drinking water. All drinking water is supplied by the Ship Creek Dam Reservoir located in the foothills of the Chugach Mountain Range east of the Post.

4.1.1 Human Health Risk Assessment

An assessment of human health involves a four-step process: identification of contaminants of potential concern (COPCs), an exposure assessment for the population at risk, an assessment of contaminant toxicity, and a quantitative characterization of the risk.

4.1.1.1 Contaminants of Potential Concern

A screening analysis was conducted to identify the COPCs. Before screening, detection limits were evaluated. In the first step of the screening, COPCs were selected based on a very conservative estimate of potential health risk. Maximum concentrations of chemicals in media (e.g., soil and groundwater) on the site were compared to conservative RBCs. For this ROD, the RBCs reflect residential exposure assumptions of 1×10^{-6} for soil and groundwater, or a hazard quotient (HQ) of 1.0 for all media. These criteria differ from the criteria used in the 1995 OU-A RI Report, which applies screening criteria of 1×10^{-7} for groundwater and an HQ of 0.1, which were determined to

Final

August 8, 1997

be overly conservative by the Agencies. Inorganic chemical concentrations were compared to naturally occurring background levels in the 1995 OU-A RI Report.

The final list of COPCs for soil and groundwater is shown in Table 4-1. The potential for these COPCs to impact health was evaluated further using site-specific exposure assumptions.

4.1.1.2 Exposure Assessment

The exposure assessment estimates the type and magnitude of exposures to the COCs at the site. The exposure assessment considers the current and potential future uses of the site, characterizes the potentially exposed populations, identifies the important exposure pathways, and quantifies the intake of each COC from each medium for each population at risk.

An exposure pathway is the mechanism by which chemicals migrate from their source or point of release to the population at risk. A complete exposure pathway comprises four elements: a source of a chemical release, transport of contaminants through environmental media, a point of potential human contact with a contaminated medium, and entry into the body or exposure route.

Under current land use conditions, individuals potentially could be exposed to COPCs in soil by ingesting soil and inhaling vapors and dust. Exposures to groundwater were not evaluated because the groundwater beneath OU-A is between 80 feet to 160 feet BGS and is not used for drinking purposes. Figures 3-1, 3-2, and 3-3 identify the potential complete exposure routes for OU-A.

EPA's Superfund guidance recommends that the reasonable maximum exposure (RME) be used to calculate potential health impacts at Superfund sites. The RME is the highest exposure that is reasonably expected to occur at the source areas and is calculated using conservative assumptions to represent exposures that are reasonable and protective. The estimated risks associated with the contaminants at OU-A are presented in Table 4-2. The risks presented are overly conservative (i.e., health-protective) because they are based on future residential land use, which is not likely at this site, thereby overestimating risk for site-specific exposure scenarios.

To estimate exposures, data regarding the concentration of COCs in the media of concern at the site (the exposure point concentrations [EPCs]) are combined with information about the projected behaviors and characteristics of the people who potentially may be exposed to these media (exposure parameters).

To estimate EPCs in soil, the 95% upper confidence level (UCL) on the mean was calculated. If the 95% UCL was greater than the maximum detected concentration, then the maximum detected concentration was used as the EPC; otherwise, the 95% UCL was used. If data sets contained fewer than 10 samples, then the maximum detected concentration was used as the EPC. EPCs were calculated for the RME and average exposure.

Exposure parameters used to calculate the RME include body weight, age contact rate, frequency of exposure, and exposure duration. Exposure parameters were obtained from EPA, Region X, Risk Assessment guidance (*EPA, Region X Supplemental Risk Assessment Guidance for Superfund*; EPA

Final

August 8, 1997

1991). The default exposure factors were modified to reflect site-specific climatological and other factors at Fort Richardson. Site-specific exposure assumptions were made for soil contact, including ingestion, dermal contact, and inhaling vapors and dust, based on snow cover for four months of the year. Exposures were estimated assuming long-term exposures to site contaminants.

4.1.1.3 Toxicity Assessment

Toxicity information was provided in the Risk Assessment for the COPCs. Generally, cancer risks are calculated using toxicity factors known as *slope factors (SFs)*, while noncancer risks are assessed using RfDs.

EPA developed SFs for estimating excess lifetime cancer risk associated with exposure to potential carcinogens. SFs are expressed in units of milligrams per kilogram per day (mg/kg-day)⁻¹ and are multiplied by the estimated intake of a potential carcinogen, in mg/kg-day , to provide an upper-bound estimate of the excess lifetime cancer risk associated with exposure at that intake level. The term *upper-bound* reflects the conservative estimate of the risks calculated from the SF. Use of this approach makes underestimates of the actual cancer risk highly unlikely. SFs are derived from the results of human epidemiological studies, or chronic animal bioassay data, to which mathematical interpolation from high to low doses, and from animal to human studies, has been applied.

EPA developed RfDs to indicate the potential for adverse health effects from exposure to chemicals exhibiting noncarcinogenic effects. RfDs, which are expressed in units of mg/kg-day , are estimates of lifetime daily exposure for humans, including sensitive subpopulations likely to be without risk of adverse effect. Estimated intakes of COCs from environmental media (e.g., the amount of a COC ingested from contaminated drinking water) can be compared to the RfD. RfDs are derived from human epidemiological studies or animal studies to which uncertainty factors have been applied.

The Risk Assessment relied on oral and inhalation SFs and RfDs. Toxicity factors were obtained from the Integrated Risk Information System (IRIS) or, if no IRIS values were available, from the Health Effects Assessment Summary Table (HEAST). For the few chemicals that did not have toxicity values available, sources other than IRIS and HEAST were used.

4.1.1.4 Risk Characterization

The purpose of the risk characterization is to integrate the results of the exposure and toxicity assessments to estimate risk to humans from exposure to site contaminants. Risks were calculated for carcinogenic and noncarcinogenic effects based on the RME. Excess lifetime cancer risk is calculated by multiplying the SF by the quantitative estimate of exposure: the chronic daily intake. These risks are probabilities generally expressed in scientific notation (e.g., 1×10^{-6}). An excess lifetime cancer risk of 1×10^{-6} indicates that an individual has a 1 in 1 million chance of developing cancer as a result of a site-related exposure to a carcinogen under the specific exposure conditions assumed. EPA considers that an excess lifetime cancer risk between 1 in 1 million (1×10^{-6}) and 1 in 10,000 (1×10^{-4}) is within the generally acceptable range; risks greater than 1 in 10,000 usually suggest the need to take action at a site.

Final

August 8, 1997

The potential for noncarcinogenic effects is evaluated by comparing an exposure level over a specified time period (lifetime) to an RfD derived for a similar exposure period. The ratio of exposure to toxicity is called an *HQ*. HQs are calculated by dividing the exposure by the specific RfD. If the HQ is less than 1, then adverse health effects are not likely to occur. By adding the HQs for all COCs that affect the same target organ (liver, nervous system, etc.), the HI can be calculated. In defining effects from exposure to noncancer-causing contaminants, EPA considers acceptable exposure levels as those that do not adversely affect humans over their expected lifetime, with a built-in margin of safety.

Soil

Under current land use conditions, the estimates of carcinogenic and noncarcinogenic effects for OU-A fell within or below the acceptable risk range for CERCLA sites. The only complete exposure pathway under current land use conditions was recreational exposure to surface soil at the Fire Training Area (see Table 4-3). The other OU-A sites do not have complete exposure pathways under current land use conditions.

At the Fire Training Area, excess lifetime cancer risks greater than or equal to 1×10^{-6} were determined only for potential future RME exposures to soil (3×10^{-6}).

At the cesspool area of the Transmitter Site, potential excess lifetime cancer risks greater than 1×10^{-6} were calculated for potential future RME industrial and residential exposures to soil (1×10^{-5} and 5×10^{-5} , respectively).

While sludge contained in the Dry Well was not evaluated directly in the Risk Assessment because of the lack of exposure pathways, this material is contaminated and could present a health risk if contacted by humans. Sludge in the Dry Well will be removed and disposed of during summer 1997 to eliminate this potential threat.

Under future exposure conditions, no noncancer HIs exceeded EPA's regulatory benchmark of 1 for any exposure scenario at any OU-A site.

The results of the baseline HHRA indicated that for soil exposure pathways, the estimated cumulative potential cancer risks for all current and future exposure scenarios at all OU-A source areas do not represent unacceptable risks to human health, based on EPA criteria.

Groundwater

No COPCs were identified in groundwater at the Fire Training Area or the Transmitter Site. Furthermore, exposures to groundwater at these source areas were considered to be incomplete exposure pathways. Two COPCs, chloroform and manganese, were identified at the Dry Well. Groundwater at the Dry Well is not used as a source of potable water. Therefore, exposure to groundwater under current land use conditions at the Dry Well represents an incomplete exposure pathway. The HHRA concluded that the estimated cumulative potential cancer risks at the Dry Well for hypothetical future groundwater exposure pathways would fall within or below the range of

Final

August 8, 1997

acceptable risks as established by the EPA Superfund program. For noncarcinogenic effects, the regulatory benchmark of a total HI of 1 was not exceeded at any wells at the Dry Well. Removal of contaminated sludge and soil will occur in 1997, further reducing potential threats to future groundwater users.

Uncertainties associated with the baseline HHRA also affect the degree of confidence that can be placed in risk characterization results. The principal uncertainties associated with the OU-A HHRA process, which could result in overly conservative risk evaluations, are summarized below:

- Chloroform was detected in groundwater samples from two wells at the Dry Well. This analyte is a common laboratory contaminant. Because no evidence exists to suggest that chloroform is a site-related contaminant, the risks presented in this section should be regarded with caution;
- Based on results of previous investigations, the presence of manganese in the groundwater samples is likely attributable to naturally occurring minerals in groundwater at the site;
- Future surface soil concentrations were derived from subsurface soil data up to 15 feet BGS. The assumption that subsurface soil would be disturbed and mixed with the present surface soil layer represents a conservative approach; and
- The most conservative exposure scenarios evaluated in the baseline HHRA involved residential exposure assumptions. If future residential development of OU-A source areas does not occur, then the risk estimates for this exposure scenario greatly overestimate actual future site risks. Note that future residential development is not anticipated; rather, land use is expected to remain the same in the future.

Because numerous conservative assumptions were used in the selection of COPCs and the exposure and toxicity assessments, the risk characterization results likely overestimate risks associated with COPCs at OU-A.

4.1.2 Ecological Risk Assessment

The ERA performed for OU-A addressed the impacts and potential risks posed by source-related contaminants to natural habitats, including plants and animals, in the absence of remedial action. Unlike the HHRA, the ERA focused on the contaminants' effects on populations or communities, rather than individuals. If identified during the ERA, potential risks to individuals of a species are evaluated within a larger context to determine ecological significance.

The masked shrew, red fox, robin, and kestrel were selected as representative terrestrial site receptors

Final

August 8, 1997

for OU-A based on site-specific exposure pathways and ecological considerations. The potential for adverse effects from contaminants of ecological concern (COECs) on plant communities and aquatic invertebrates also was evaluated.

Risk estimation involves calculating HQs to assess potential ecological risks to measurement species and communities. Ecological effects are quantified by calculating the ratio between a chemical of potential ecological concern's (COPEC's) estimated intake or concentration and its corresponding toxicity reference value (i.e., the intake level or concentration at which no adverse ecological effects are expected to occur). If this ratio (i.e., the HQ) is less than 1, then adverse ecological effects are not expected for the COPEC. This ratio is a summation of all site contaminants. The HQs described in this summary were calculated using conservative RME assumptions.

Based on the risk analysis, COEC concentrations at OU-A result in negligible risk to small-mammal populations, aquatic invertebrates, emergent wetland vegetation, and upland plant vegetation. The overall potential for valued environmental resources at this site to be adversely affected is considered negligible.

The ERA is subject to uncertainties because virtually every step in the Risk Assessment process involves assumptions using professional judgment. Principal uncertainties associated with the OU-A ERA include the following:

- Avian and mammalian bioaccumulation factors were unavailable for many COPECs, which resulted in an underestimation of potential risks to measurement species; and
- Most of the available toxicity values were determined using laboratory animals under laboratory conditions. These values, as well as toxicity values determined based on indirect effect measures (such as increased body weight), may not be representative of other significant indirect effects (such as behavioral changes) realized in free-ranging wildlife.

Reasonable and conservative assumptions were used in the ERA when empirical data were unavailable. Consequently, potential ecological risks to OU-A species are more likely to be overestimated rather than underestimated.

4.1.3 Summary of Risks

The conclusion of the baseline Risk Assessment for OU-A is that contaminant levels in soil and groundwater at the OU-A sites do not represent unacceptable risks to human health or the environment, based on EPA criteria. However, the levels of petroleum contamination in the soil do exceed the ADEC soil cleanup criteria. While sludge within the Dry Well may pose a threat to human health, this material will be removed and disposed of in 1997. The Army, ADEC, and EPA have elected to pursue further cleanup efforts at these sites under the Two-Party Agreement. Under the Two-Party Agreement, the Army and ADEC will clean up contaminated materials at each site in

Final

August 8, 1997

accordance with applicable State of Alaska regulations. While the specific cleanup actions and the time required to remediate the sites have yet to be determined, the Army and State of Alaska will jointly consider all available information before selecting appropriate OU-A site cleanup activities. Decisions regarding OU-A site cleanup will be documented in accordance with stipulations of the Two-Party Agreement. Because the OU-A source areas will be addressed through the Two-Party Agreement, they are not discussed further in this ROD.

4.2 OPERABLE UNIT B

4.2.1 Human Health Risk Assessment

The OU-B Risk Assessment identified ways that people working or living on or near the source areas could be exposed to contaminated media: touching and ingesting soil, inhaling vapors and dust released from soil, and using groundwater for drinking and showering. On-site workers and visitors are the individuals most likely to be exposed under current exposure conditions. Current use of Poleline Road is limited to periodic visits by authorized personnel, and by trespassers or open space recreational users. Under potential future land use conditions, exposures to on-site workers, visitors, residents, or downgradient groundwater users are possible. Table 4-4 lists the exposure pathways evaluated at OU-B.

Based on analytical results from surface and subsurface soil surrounding Areas A-1 and A-2, the risk of cancer and noncancer health effects from exposure to low concentrations of solvents in soil was negligible. The excess lifetime cancer risk was 1 in 100,000 (1×10^{-5}), and the noncarcinogenic HI was less than 1 for residential exposure to soils at 0 feet to 15 feet BGS in Areas A-3 and A-4. Generally, remediation is not warranted for protection of public health if the total lifetime excess cancer risk does not exceed 1 in 10,000 and if noncarcinogenic effects have an HI of less than 1. However, although these contaminants in soil do not pose a threat to human health, they may serve as a continuing source of contamination to groundwater.

Excess lifetime cancer risks for soil in the "hot spot" area beneath Area A-3 (see Figure 3-6) and the hillside were not within the acceptable risk range for the current-worker exposure scenario. However, these soils are 14 feet BGS; therefore, the likelihood of direct exposure to humans is unlikely.

The NCP and state regulations require protection and restoration of water resources. Contamination of OU-B groundwater, if used as a drinking water source, presents an unacceptable risk to human health. The "hot spot" area beneath Area A-3 and the hillside presents a continuing source of contamination to the groundwater at the site. Table 4-5 summarizes the maximum possible human risks associated with the various locations at the site and the risks to humans if groundwater from different depths at the site is ingested.

Groundwater at OU-B is not used, and there are no residents or wells downgradient of the site. There are no current plans for commercial or residential development in the site area. Additionally, groundwater transport modeling was used to estimate time of travel for detectable concentrations of TCE and 1,1,2,2-tetrachloroethane (0.005 mg/L) with no depletion or remediation of the contaminant

Final

August 8, 1997

source and no biodegradation over time. The modeled transport time for 0.005 mg/L of TCE to reach the Eagle River is approximately 120 years, and for 1,1,2,2-tetrachloroethane, 170 years. Concentrations of 0.005 mg/L of TCE and 1,1,2,2-tetrachloroethane do not exceed conservative exposure assumptions, nor do they exceed Alaska Water Quality Standards for ingestion of freshwater organisms. Therefore, concentrations in the leading edge of the plume, if it were to reach the Eagle River, would not pose a threat to human health.

The principal uncertainties associated with the OU-B HHRA process, which could result in overly conservative risk evaluations, are summarized below:

- Detection limits for the field screening analytical method for VOCs in soil were higher than those for the laboratory analytical method (about 0.005 mg/kg) and were higher than many detected values from laboratory sampling results. The higher detection limits in field screening samples add uncertainty to the estimates of VOC EPCs;
- Hazard/risk results were assessed based on on-site residential exposure scenarios that assumed an exposure frequency of 350 days per year; an exposure duration (ED) of 30 years; and daily intake rates for soil, air, and water based on an exposure time of 24 hours per day. The potential for future residential development is remote. Exposure of current and possible future receptors at Poleline Road would be much less than that for the residential scenario. Therefore, hazard/risk results reported in the HHRA will overestimate risk to current and possible future receptors; and
- For the purpose of evaluating risk from exposure to groundwater at Poleline Road, it was assumed that groundwater was used for household purposes, including drinking water. However, the potential for residential or commercial development and groundwater use is remote. Therefore, the calculated risk levels do not represent actual risks under current or probable future exposure conditions. In addition, an alternative water supply (pipeline from Eklutna Lake) could meet future water demands near the site, if developed.

4.2.2 Ecological Risk Assessment

The ERA performed for OU-B addressed the impacts and potential risks posed by contaminants to natural habitats, including plants and animals, in the absence of remedial action. Unlike the HHRA, the ERA focuses on the effects to populations or communities of plants and animals, not individuals. If identified during the ERA, potential risks to individuals of a species are evaluated within a larger context to determine ecological significance.

The northern red-backed vole and muskrat were selected as representative terrestrial site receptors for

Final

August 8, 1997

OU-B based on site-specific exposure pathways and ecological considerations. The potential for adverse effects from COECs on plant communities and aquatic invertebrates also was evaluated.

Based on the risk analysis, COEC concentrations at OU-B result in a negligible risk to small-mammal populations, aquatic invertebrates, emergent wetland vegetation, and upland plant vegetation. The overall potential for valued environmental resources at this site to be adversely affected is considered negligible.

The ERA is subject to uncertainties because virtually every step in the Risk Assessment process involves assumptions using professional judgment. Principal uncertainties associated with the OU-B ERA include the following:

- ED and area use by potential receptors assumed a worst-case scenario. Area usage by receptors was assumed conservatively to be 100%. It is also assumed that exposure to contaminated soils and vegetation is continuous. Because mobile receptors are likely to feed at or visit several locations, or avoid VOC-contaminated areas, their daily dose, if averaged over time, could be less than that used in this ERA for evaluating risk. Adverse effects in small, localized areas on a few small-mammal individuals are negligible considerations in terms of risk to the biological population;
- No standardized system is available for identifying toxicity-based "safe" benchmark values for terrestrial wildlife. The potential exists for wildlife species to be more or less sensitive than test species (some biota adapt) and the toxicological benchmarks used. Toxic dose values for laboratory organisms also may be substantially lower than those for wildlife because of the sensitive strain of laboratory animals used and the direct means by which they are dosed. LD₅₀ studies usually are designed to promote maximum exposure (absorption) and to lessen any chemical complexing with dietary material. The LD₅₀ dietary studies probably provide a better indication of the toxicity of the chemical tested, while no observed adverse effect levels from longer studies are the best laboratory studies to use as predictors of field effects; and
- Groundwater at the site is contaminated with VOCs. However, there are no known on-site or off-site seeps by which wildlife can be exposed. It was assumed that groundwater at the site and the contamination within the groundwater eventually could reach the Eagle River. There is a lack of information regarding migration of the groundwater beneath the site. However, an evaluation of the modeled groundwater data indicates that because of time of travel and concentrations required for toxic effects, the additional risk estimate is negligible.

Final

August 8, 1997

Because numerous conservative assumptions were used in the selection of COECs and the exposure and toxicity assessments, the risk characterization results likely overestimate risks associated with COECs at OU-B.

4.2.3 Summary of Risks

Exposure scenarios associated with OU-B soil do not exceed EPA's acceptable excess cancer risk/HIs for human health and ecological receptors. Although excess lifetime cancer risks and HIs for soil at the "hot spot" area beneath Area A-3 exceed EPA's acceptable risk ranges, the contaminants are found at 14 feet BGS and therefore do not pose a hazard for direct human contact.

While soil contamination does not pose a threat to human health or the environment, the contamination level is high enough to pose an ongoing threat to groundwater. Groundwater contamination in the shallow and deep zones exceeds EPA's acceptable risk range and state and federal drinking water MCLs for human consumption. The NCP and state regulations require protection and restoration of water resources. Contamination of OU-B groundwater, if used as a drinking water source, presents an unacceptable risk to human health. Therefore, groundwater and the "hot spot" source at Poleline Road require remedial action. The Army, ADEC, and EPA have selected a preferred remedial alternative for OU-B based on criteria found in the NCP.

August 8, 1997

5.0 DESCRIPTION OF ALTERNATIVES

5.1 NEED FOR REMEDIAL ACTION

Actual or threatened releases of hazardous substances (chlorinated solvents) from Poleline Road, if not addressed by implementing the response action selected in this ROD, may present an imminent and substantial endangerment to public health, public welfare, or the environment.

The specific reasons for conducting remedial actions at Poleline Road are provided below, with the main focus being protection of groundwater in accordance with the NCP Groundwater Protection Strategy:

- VOCs (i.e., PCE; TCE; and 1,1,2,2-tetrachloroethane) in groundwater at Poleline Road are present at concentrations above state and federal MCLs and risk-based criteria; and
- VOCs, including PCE; TCE; and 1,1,2,2-tetrachloroethane, in contaminated soils are a continuing source of groundwater contamination.

5.2 REMEDIAL ACTION OBJECTIVES

As a part of the RI/FS process, remedial action objective (RAOs) were developed in accordance with the NCP and EPA guidance for conducting RI/FS investigations. The purpose of the objectives is to reduce the contamination in the groundwater at OU-B to levels that do not pose a threat to human health and the environment. If the OU-B area were converted to public domain at any time in the future, the residents would not be at risk from use of the groundwater.

The objectives of remedial action at OU-B are as follows:

- Reduce contaminant levels in the groundwater to comply with drinking water standards;
- Prevent contaminated soil from continuing to act as a source of groundwater contamination;
- Prevent the contaminated groundwater from adversely affecting the Eagle River surface water and sediments; and
- Minimize degradation of the State of Alaska's groundwater resources at the site as a result of past disposal practices.

Tables 5-1 and 5-2 summarize the chemical-specific cleanup goals for groundwater and soil at Poleline Road.

Final

August 8, 1997

RAOs are based on either human health risk estimates that exceed or fall within the 1×10^{-6} to 1×10^{-4} risk range or on federal and state applicable or relevant and appropriate requirements (ARARs). All groundwater RAOs are based on state and federal MCLs, with the exception of 1,1,2,2-tetrachloroethane. The RAO for 1,1,2,2-tetrachloroethane is based on the RBC for this chemical in residential drinking water. RAOs for soil are based on protection of the groundwater from leaching of the contaminants (EPA, Region 3, RBCs): 1,1,2,2-tetrachloroethane—0.1 mg/kg and PCE—4.0 mg/kg.

Monitoring at Poleline Road will be conducted to ensure that RAOs are achieved. The goal of this monitoring will be:

- To ensure that no off-source migration of contaminants is occurring;
- To indicate contaminant concentrations and compliance with state and federal MCLs; and
- To indicate whether remedial action is effective or needs modification.

5.3 SIGNIFICANT APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS

A full list of ARARs is in Section 8. The following ARAR is the most significant regulation that applies to the remedy selections for Poleline Road:

- State and federal MCLs are relevant and appropriate for groundwater. These MCLs set the active remediation goals for groundwater contaminants regulated by state and federal drinking water regulations.

5.4 DESCRIPTION OF ALTERNATIVES

Many technologies were considered to clean up the contaminated soil and groundwater at OU-B. Appropriate technologies were identified and screened for applicability to site conditions. The potential technologies then were combined into media-specific sitewide alternatives. Potential remedial alternatives for OU-B were identified, screened, and evaluated in the FS.

During the development of the FS, a Treatability Study was performed to evaluate the effectiveness of several remedial technologies included in the FS. The results of the Treatability Study indicated that AS of chlorinated solvents in groundwater would not effectively treat contaminants to levels below state and federal MCLs. In addition, the Treatability Study indicated that biological components of natural attenuation would not be an important degradation mechanism of chlorinated solvents in the groundwater system at Poleline Road.

Final

August 8, 1997

The following are alternatives evaluated in the Proposed Plan.

Alternative 1: No Action

CERCLA requires evaluation of a no-action alternative as a baseline reflecting current conditions without any cleanup effort. This alternative is used for comparison to each of the other alternatives and does not include monitoring or institutional controls. No costs would be associated with this alternative.

Alternative 2: Monitored Natural Attenuation

Natural attenuation, or breakdown of contaminants without artificial stimuli, includes institutional controls and groundwater monitoring to determine whether the contaminants in the groundwater are degrading naturally. Natural attenuation can occur because of degradation processes such as biological breakdown, chemical and physical processes, and volatilization. Even under ideal conditions, entire breakdown of contaminants is rarely complete.

Institutional controls for Poleline Road could include access restrictions (i.e., posted signs; fencing around the area; 6-foot, industrial-grade security fencing with appropriate entry gates; restrictions on future land use; restrictions on groundwater well installation; restrictions on the use of wells; and well use advisories). Such institutional controls would not reduce the source of contamination. While the VOC-contaminated source area would remain as it exists, the concentrations in the groundwater would be reduced by natural processes. However, institutional controls would decrease or minimize human or wildlife exposure to contaminants. Periodic inspections and maintenance of the institutional controls would be conducted.

Environmental monitoring would be performed to obtain information regarding the effectiveness of the attenuation process in remediating the contamination as well as to track the extent of contaminant migration from the site. Approximately two additional wells would be added to the 15 existing wells. These wells would be screened in geological zones hydraulically connected with the contamination source, supplemented by installing groundwater monitoring wells when required. Upgradient wells would be used to provide information regarding the background groundwater quality at a source. All monitoring of downgradient wells necessary to determine the effectiveness of natural attenuation would be performed.

Monitoring would include analysis for the contaminants that exceed the RAOs and associated breakdown products for Poleline Road. Sample collection, analysis, and data evaluation would continue until sufficient data regarding changes in contaminant plume migration and attenuation rates are gathered. Evaluation would include potential seasonal fluctuations in groundwater contaminant concentrations. The frequency of monitoring would be defined during the post-ROD activities.

The total estimated present worth cost of this alternative is \$1,300,000, which includes \$80,000 for capital costs, \$29,070 per year for annual operation and maintenance (O&M), and \$29,070 per year for annual groundwater monitoring. For costing purposes, it was assumed that the fencing would be installed around the area of contamination. The estimated time frame for cleanup goals to be

Final

August 8, 1997

achieved and for monitoring to be performed was 500 years, although the cost estimate includes 30 years of annual operation costs.

Alternative 3: Containment

The objective of containment is to minimize water flow into or out of contaminated areas, thus minimizing migration of contamination into lower aquifers. This alternative consists of a cap and vertical barrier to reduce the mobility of the contaminants, monitoring, and institutional controls. See Alternative 2 for a description of monitoring and institutional controls. Site soils would be covered with a layer of sand overlying an impermeable synthetic membrane to minimize the amount of surface water and rainwater infiltrating through the contaminated soils. Covering the soils would protect humans and animals from contacting contaminated soils. Bentonite slurry walls would be installed to inhibit the flow of water from the wetlands into the site. Without this flow, the mobility of the contaminants in the soil would be reduced.

Existing groundwater contamination outside the source area would be expected to meet RAOs through natural attenuation. Because the soils would be capped and surface water flow controlled, production of leachate is expected to significantly decrease; therefore, groundwater would be expected to naturally attenuate faster than if no cap were placed on the soils.

Groundwater monitoring/evaluation would be performed to assess when the groundwater naturally attenuates and to evaluate any impact to potential downgradient receptors.

The estimated total present worth for this alternative is \$2,500,000, which includes \$993,325 for capital costs, \$9,600 per year for annual O&M, and \$20,620 per year for annual groundwater monitoring. For costing purposes, it was assumed that the fencing would be installed around the area of contamination. The estimated time frame for cleanup goals to be achieved and for monitoring to be performed was 500 years, although the cost estimate includes 30 years of annual operation costs.

Alternative 4: Interception Trench, Air Stripping, and Soil Vapor Extraction

The objective of this alternative is to remove contamination from the soil and groundwater within Areas A-1 through A-4. Trenches would be dug for collection of groundwater, which would be pumped to an air stripper for treatment. Air stripping is a process that removes VOCs by transferring them from contaminated water to air. Vapors from the air stripper would be treated as required by state and federal regulations before being discharged to the atmosphere. SVE is an in-place process for removal of VOCs from unsaturated soils. The system consists of a series of vapor extraction wells, commonly called *vapor extraction points*, and air blowers to draw air through the soil and in the VEPs. SVE includes piping to collect the extracted air and systems to remove contaminants from the extracted air as required by state and federal regulations before being discharged. Long-term monitoring of groundwater to evaluate system performance is also a component of this alternative.

The estimated total present worth for this alternative is \$7,500,000, which includes \$2,042,000 for capital costs, \$142,880 per year for annual O&M, and \$20,620 per year for annual groundwater monitoring. For costing purposes, it was assumed that the fencing would be installed around the area

Final

August 8, 1997

of contamination. The estimated time frame for cleanup goals to be achieved through active treatment is five years, and 135 years is estimated for the remainder of the plume to achieve cleanup goals. The cost estimate includes 30 years of annual operation costs.

Alternative 5: Air Sparging and Soil Vapor Extraction of the "Hot Spot" and Monitored Natural Attenuation

The objective of this alternative is to remove contamination from the "hot spot" and to rely on natural attenuation to restore the remainder of the contaminated groundwater plume. AS is the injection of pressurized air into the shallow aquifer, which results in volatilization of VOCs and enhanced biodegradation of contaminants susceptible to aerobic microbial degradation. SVE is used commonly in combination with AS. See Alternative 4 for a description of SVE. See Alternative 2 (Section 7.1) for a description of groundwater monitoring and institutional controls for Poleline Road.

The estimated total present worth for this alternative is \$5,500,000, which includes \$1,600,000 for capital costs, \$72,736 per year for annual O&M, and \$29,070 per year for annual groundwater monitoring. For costing purposes, it was assumed that the fencing would be installed around the area of contamination. The estimated time frame for cleanup goals to be achieved and for monitoring to be performed was 150 years, although the cost estimate includes 30 years of annual operation costs.

Alternative 6: High-Vacuum Extraction of the "Hot Spot" and Institutional Controls with Long-Term Groundwater Monitoring

The objective of this alternative is to remove the contamination from the "hot spot" and to monitor the remainder of the contaminated plume in the groundwater to assess the progress of natural attenuation and/or plume migration. This action ensures that removing the source inhibits further migration of the contaminants into the groundwater. The monitoring will be conducted to determine whether the plume is expanding beyond the boundaries of Poleline Road. This alternative also includes enforcement of land use restrictions designed to prohibit extraction and use of the groundwater, periodic groundwater monitoring to track the progress of contaminant breakdown and movement, and an early indication of unforeseen environmental or human health risk. The high-vacuum extraction (HVE) process uses a strong vacuum from the "hot spot" to extract contaminated soil vapors and some contaminated groundwater. As this air and water moisture is drawn to the surface, some of the contaminants in the water will transfer to the air. An air stripping system will be used to treat the extracted groundwater to meet state and federal MCLs before the groundwater is reinjected into the deep aquifer. Soil vapors extracted from the "hot spot" soil will be treated as necessary to meet state and federal air quality standards before being released to the atmosphere.

The estimated total present worth for this alternative is \$4,000,000, which includes \$801,841 for capital costs, \$64,878 per year for annual O&M, and \$29,070 per year for annual groundwater monitoring. For costing purposes, it was assumed that the fencing would be installed around the area of contamination. The estimated time frame for cleanup goals to be achieved in the "hot spot" is seven to 12 years. The estimate for the remainder of the plume to remediate and for monitoring to be performed was 150 years, although the cost estimate includes 30 years of annual operation costs.

Table 5-1 REMEDIAL CLEANUP GOALS FOR GROUNDWATER POLELINE ROAD DISPOSAL AREA FORT RICHARDSON, ALASKA			
Contaminant of Concern	Maximum Detected Concentration (mg/L)	Remedial Action Objective (mg/L)	Source of RAO^a
Benzene	2.9	0.005	MCL
Carbon Tetrachloride	2.6	0.005	MCL

6.0 SUMMARY OF COMPARATIVE ANALYSIS OF ALTERNATIVES

The selection of alternatives was based on an evaluation using the nine Superfund criteria specified in Table 6-1. The first two criteria are known as *threshold* criteria that must be met by all selected remedial actions. The following five criteria are known as *balancing* criteria, and the final two criteria as *modifying* criteria.

6.1 THRESHOLD CRITERIA

Overall Protection of Human Health and the Environment

Alternatives 4 and 6 would provide the greatest protection to human health and the environment by actively treating VOC-contaminated soil and groundwater. Treatability Studies indicated that Alternative 5 would not reduce on-site contamination effectively, thereby not providing protection of human health and the environment. Alternative 3 would protect human health and the environment by reducing the possibility of human contact with contaminants and minimizing future infiltration of contaminants from soil to groundwater. Alternative 2 would rely on natural processes to slowly decrease contaminant concentrations in the soil and groundwater. Alternative 2 does not protect human health and the environment based on Treatability Study results that indicated no evidence of biodegradation. Alternative 2 would provide some protection of human health and the environment through institutional controls, which would reduce contact with contamination. Alternative 1 (no action) would be the least-protective alternative.

Compliance with Applicable or Relevant and Appropriate Requirements

Significant ARARs that apply to the OU-B site include the Federal Safe Drinking Water Act, Alaska Drinking Water Regulations, and the Clean Water Act. Alaska Water Quality Standards (AWQS) are also applicable requirements (see Section 8.2). However, state and federal MCLs have been used to set the remediation goals for OU-B. The AWQS eventually would be achieved through monitored natural attenuation under all of the alternatives, except no action. Alternatives 4, 5, and 6 are expected to meet all state and federal ARARs. These alternatives include active soil and groundwater treatment and would be expected to achieve state and federal standards more rapidly than Alternatives 1, 2, and 3. Alternatives 1, 2, and 3 would rely on natural processes that slowly decrease soil and groundwater to attain cleanup standards. However, under Alternative 1, no monitoring would be conducted to determine compliance with the ARARs.

6.2 BALANCING CRITERIA

Long-Term Effectiveness and Permanence

Alternatives 4 and 6 would involve permanent and active reduction of soil and groundwater contamination and would achieve long-term effectiveness. Alternative 4 would not be effective at reducing contamination, based on Treatability Study results. None of the contaminants would be addressed by Alternatives 1, 2, or 3, except through natural processes. Therefore, Alternatives 1, 2, and 3 would provide the least-effective long-term permanence.

Final

August 8, 1997

Reduction of Toxicity, Mobility, and Volume Through Treatment

Alternatives 4 and 6 would involve treatment technologies that effectively reduce the toxicity and mobility of VOC-contaminated soil and groundwater. Alternative 5 would not reduce contamination, as shown by Treatability Studies. The other alternatives do not include treatment technologies to reduce site risks. Alternative 3 would reduce contaminant mobility by restricting future infiltration of rainfall and snowmelt through contaminated soils to groundwater. Alternatives 1 and 2 would slowly decrease the toxicity and volume of contaminated media through natural attenuation. Because Alternative 2 includes monitoring, the rate and degree of contaminant reduction would be known.

Short-Term Effectiveness

Alternatives 3, 4, 5, and 6 would pose some short-term potential risks to on-site workers and visitors/members of the community during the time required for construction and installation of containment and treatment systems. These potential risks could be minimized by engineering and institutional controls. These alternatives are expected to achieve state and federal standards more rapidly than Alternatives 1 and 2.

Risks associated with groundwater contamination are equal for Alternatives 4 and 6. Because these alternatives actively treat groundwater contamination, contaminant levels would be expected to decrease during the same period of time of active remediation. While Alternative 4 treats groundwater more aggressively by addressing the entire plume area, the uncertainty associated with this technology's long-term effectiveness suggests that this alternative would not clean the site faster than Alternative 6. Alternatives 1, 2, and 3 do not actively treat soil or groundwater contamination; therefore, risks would not change over time, except through natural processes. Under Alternative 1, no monitoring would be conducted to determine the remediation time frame. However, the time frame for remediation is expected to be similar to Alternative 2.

Implementability

All alternatives would use readily available technologies and would be feasible to construct. Alternatives 1 and 2 would be readily implementable because they would require no additional action other than monitoring or institutional controls. A pilot-scale test study or field test would be conducted before full-scale implementation of Alternatives 4, 5, and 6.

Cost

The estimated costs for each alternative evaluated for OU-B are in Table 6-2 and are based on the information available at the time the alternatives were developed. Actual costs are likely to be within +50% to -30% of the values on the table. Appendix C includes detailed cost estimates for each of the OU-B remedial alternatives.

Final

August 8, 1997

6.3 MODIFYING CRITERIA

State Acceptance

The State of Alaska has been involved with the development of remedial alternatives for OU-B and concurs with the Army and EPA in the selection of Alternative 6. This acceptance is contingent on the following items:

- The Remedial Design and Remedial Action will include refining the contaminant fate and transport modeling based on new field data, which will be reviewed and approved by ADEC, EPA, and the Army. This refinement of the modeling is to verify whether the proposed soil RAOs are protective of groundwater, and to better evaluate the anticipated attenuation of groundwater contaminants and the time needed to achieve MCLs;
- If the modeling results indicate that soil meeting the RAOs would continue to act as a secondary source for groundwater contamination, the RAOs will be re-evaluated and modified to be protective;
- If the groundwater monitoring results indicate that contamination is migrating farther from the source area and that the Eagle River could be affected, alternative or additional remedial actions will be evaluated and, if determined appropriate, implemented; and
- Based on current land ownership, ADEC will accept natural attenuation as a treatment of groundwater for 150 years. However, if the land use changes and becomes available for development, then the department will re-evaluate whether the time frame is reasonable for the proposed use.

Community Acceptance

Community response to the preferred alternatives was generally positive. Community response to the remedial alternatives is presented in the Responsiveness Summary, which addresses comments received during the public comment period.

Summary

After evaluation of the potential risks and the appropriate cleanup standards, the preferred alternative for OU-B is Alternative 6: HVE of the "hot spot," sitewide institutional controls, natural attenuation, and long-term monitoring of groundwater.

Alternative 6, the preferred alternative, is expected to achieve overall protection of human health and

Final

August 8, 1997

the environment and to meet ARARs. Additionally, this alternative is a cost-effective and permanent solution to contamination at OU-B.

<p align="center">Table 6-1</p> <p align="center">CRITERIA FOR EVALUATION OF ALTERNATIVES</p> <p align="center">FORT RICHARDSON, ALASKA</p>

7.0 SELECTED REMEDY

Alternative 6 is the selected alternative for treating the soil and groundwater at OU-B. A thorough assessment of alternatives considered groundwater risks, cleanup times, and costs. Alternatives 1 and 2 were eliminated because they did not satisfy the threshold criteria. Alternative 3, containment, does not address the toxicity or volume of the contamination, nor does it actively treat the VOCs; therefore, it was eliminated. While Alternative 4 would remediate a larger portion of the plume, this alternative would not remediate the site noticeably faster than the selected alternative. Therefore, the additional costs are not proportional to the benefits. Preliminary results of on-site testing during fall 1996 indicate that the AS portion of Alternative 5 would not be effective at this site; therefore, this alternative was eliminated.

Protection of human health and the environment and compliance with ARARs will best be attained through cleanup of soil and groundwater in the source area, long-term monitoring of the groundwater plume, and enactment of institutional controls to prevent unrestricted use of the area. The use of HVE, a variation on SVE, is EPA's primary presumptive remedy for VOC-contaminated soils. The multi-step approach adopted in Alternative 6 is part of EPA's presumptive strategy for addressing contaminated groundwater. Figure 7-1 illustrates the key decision points and implementation strategy for the selected remedy.

Initially, the HVE system will be installed within the "hot spot" to decrease contamination and provide hydraulic containment of this area in order to prevent additional contaminant migration downgradient. While HVE directly addresses the source area, it indirectly assists in remediation of the downgradient plume by hydraulic containment of the principal threat. Periodic monitoring of groundwater within and downgradient of the "hot spot" will be performed in conjunction with this effort to determine the effectiveness of the preferred alternative in meeting the long-term groundwater restoration objectives. During this initial step of remedy implementation, Treatability Studies will be conducted to evaluate innovative technologies that may enhance the selected remedy. These technologies include, but are not limited to, soil heating and phytoremediation.

If HVE alone fails to remediate the source area within a reasonable time frame and the Treatability Studies are successful, then one of the successful technologies (i.e., soil heating) for enhanced extraction will be combined with the selected alternative (see Figure 7-1).

The "hot spot" is defined by the area containing greater than 1 mg/L 1,1,2,2-tetrachloroethane in groundwater (see Figure 3-6). This area represents the main threat at this site. Specifically, the "hot spot" is the area that contains the contamination and acts as a reservoir for migration of contamination to groundwater. Actively remediating this "hot spot" addresses the main threat. Concentrations of 1,1,2,2-tetrachloroethane and TCE that exceed the 1% solubility of these chemicals are found within the "hot spot." These high concentrations indicate a need to closely monitor for a denser-than-water nonaqueous phase liquid (DNAPL) during construction and operation of the "hot spot" treatment system.

The flat gradient of the groundwater in this area indicates decreased probability of significant contaminant transport, and the relatively low concentrations of contaminants outside the "hot spot"

Final

August 8, 1997

justify classifying the downgradient plume as a relatively low-level threat. Concurrent with implementation of the selected remedy will be monitoring of the downgradient plume to track and assess the natural attenuation of groundwater contaminants.

7.1 MAJOR COMPONENTS OF THE SELECTED REMEDY

The major components of the selected remedy include the following:

- Treat the "hot spot" through HVE of soil vapor and groundwater in the perched and shallow zones to prevent the main threat from continuing as a source of contamination to groundwater. Soil vapors extracted from the "hot spot" soil will be treated as necessary to meet state and federal air quality standards before release to the atmosphere. Extraction wells will be placed in areas of highest contamination and operated until state and federal MCLs and risk-based criteria are achieved in the "hot spot";
- Treat extracted groundwater through air stripping to achieve state and federal MCLs before discharge;
- Allow natural attenuation of groundwater contamination in areas outside the "hot spot";
- Evaluate and modify the treatment system as necessary to optimize effectiveness in achieving RAOs;
- Monitor groundwater measurements to determine the attainment of RAOs and to detect and thoroughly characterize possible DNAPL. Duration of the HVE system is expected to be from seven years to 12 years for soil and shallow groundwater in the "hot spot" and 150 years for natural attenuation of remaining groundwater to meet state and federal MCLs and risk-based criteria;
- Evaluate the effectiveness of the HVE system to meet long-term restoration goals during initial implementation;
- Conduct Treatability Studies to evaluate innovative technologies with potential to enhance the remedial action, and implement successful innovative technologies if the initial remedy proves ineffective; and
- Maintain institutional controls, including restrictions governing site access, construction, and well development, as long as hazardous substances remain at levels that preclude unrestricted use on site. Implement restrictions on groundwater until contaminant levels are below state and federal MCLs and risk-based criteria.

Final

August 8, 1997

The Army shall establish and maintain institutional controls, including restrictions governing site access, construction, road and utility maintenance, and well development (except as such wells may be required by this remedial action), as long as hazardous substances remain on site at levels that preclude unrestricted use. The Army shall implement restrictions on groundwater use until contaminant levels are below federal and state MCLs throughout the site. The Army shall ensure compliance with the institutional controls in place at the facility, because noncompliance violates a requirement of this ROD, and therefore violates a requirement of the FFA between the Army, EPA, and ADEC. The institutional controls strategy includes the following:

- To ensure long-term effectiveness of this remedy, permanent implementation processes and policies for implementing institutional controls at the site shall be developed for the period of time that the Army is in control of the real property upon which these institutional controls will be effective and during the time, if any, that the real property may be transferred to another federal agency's responsibility and control. Such processes and policies will be developed through joint EPA, ADEC, and Army negotiations. It is intended that once these implementation processes and policies are in place, this ROD will be revised to incorporate such implementation processes and policies;
- The Army shall conduct an annual review of the institutional controls being implemented by the Army for this site and shall assess, among other things, the effectiveness of the institutional controls based on a visual "walk-through" of the areas of the site where the institutional controls are in effect and a review of the documents that implement the institutional controls; and
- The Army shall notify EPA and ADEC in the event that Fort Richardson property is identified as excess to the Army's needs while hazardous substances remain at or above levels that preclude unrestricted use, and before actual transfer of land management responsibilities to another federal agency or department.

7.2 AGENCY REVIEW OF THE SELECTED REMEDY

Tables 5-1 and 5-2 present the RAOs for groundwater and soil, respectively. The goal of this remedial action is to restore groundwater to its beneficial use. While the long-term goal of the remedial action is to return all the groundwater within and outside of the source area ("hot spot") to state and federal MCLs and risk-based criteria, active remediation will be considered complete when concentrations within the "hot spot" are below remediation goals for three continuous quarters after remedy shutdown and the plume is not expanding. Based on information obtained during the RI and on careful analysis of all remedial alternatives, the Army, EPA, and ADEC believe that the selected remedy will achieve this goal. Groundwater monitoring data will be reviewed regularly to assess the progress made by the selected remedy toward the cleanup levels, and will continue in the

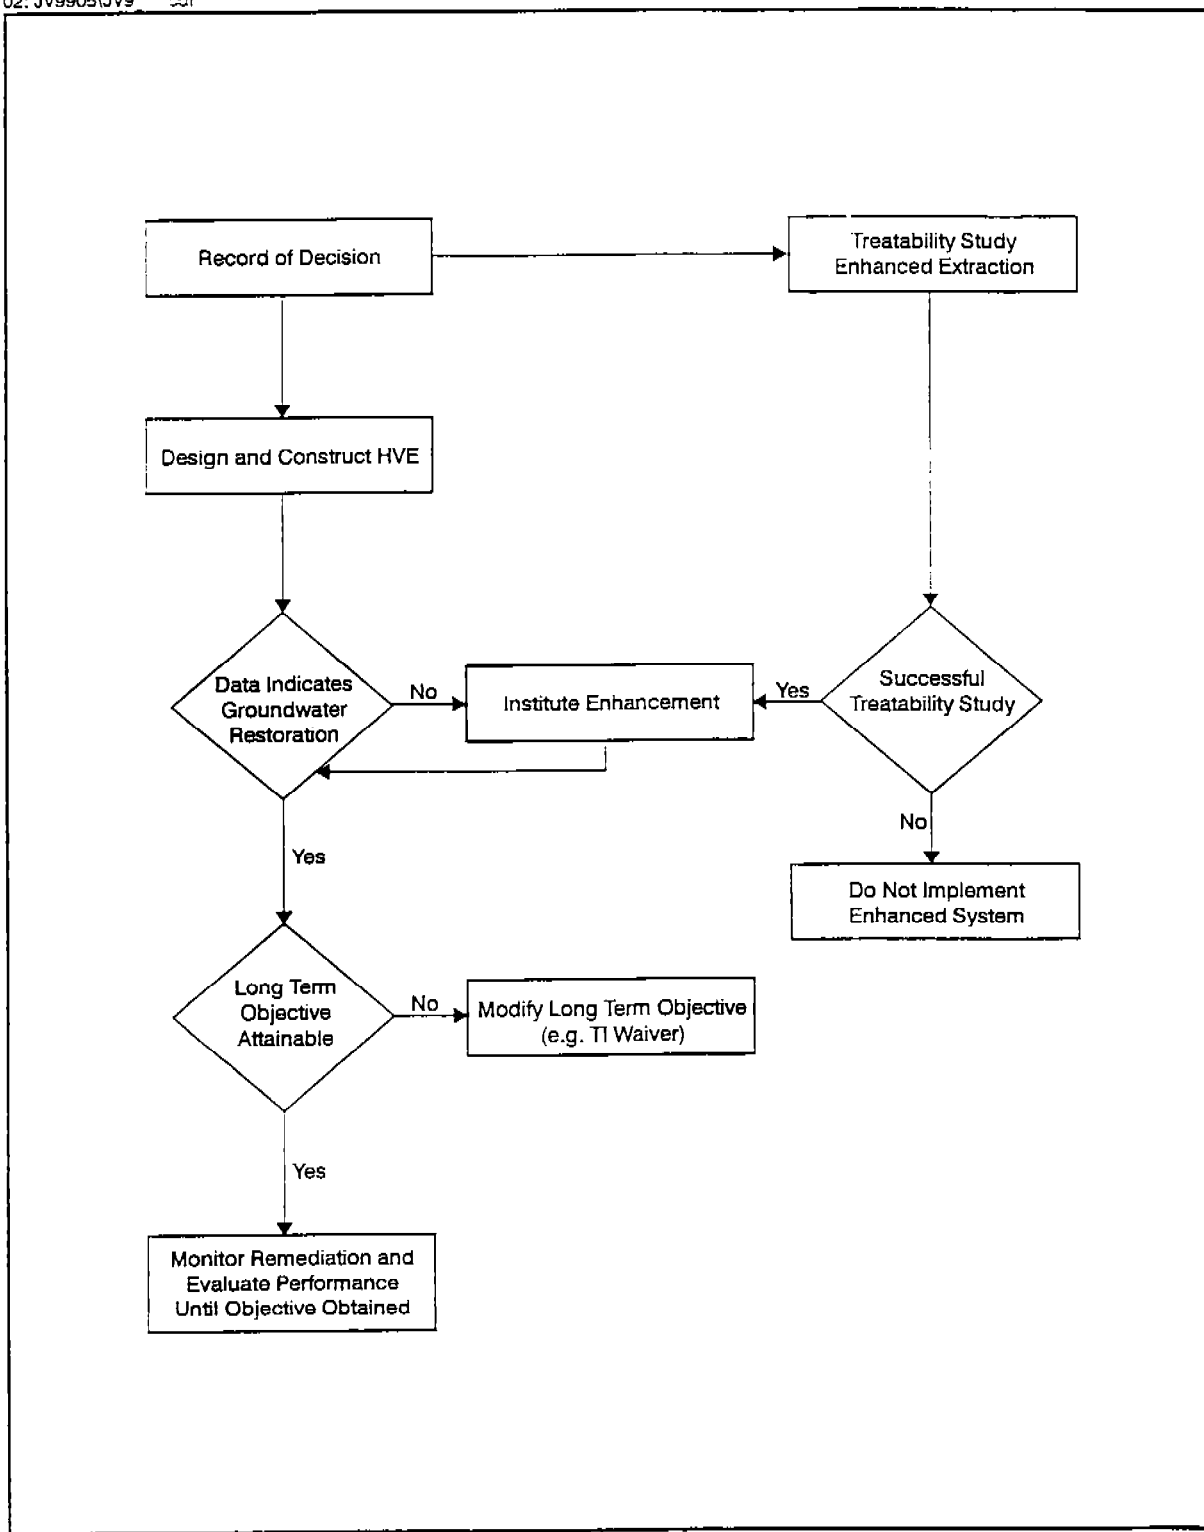

Final

August 8, 1997

downgradient portion of the plume until state and federal MCLs are achieved over three consecutive quarters and until subsequent soil borings show that RAOs are met after remedy shutdown and the plume is not expanding.

Because the remedy will result in hazardous substances remaining above regulatory levels on site, a review will be conducted within five years after commencement of the remedial action to ensure that the remedy continues to provide adequate protection of human health and the environment, and will continue for five-year increments until the remedy is complete. After five years of implementation, if monitoring and performance data indicate that the selected remedy and any enhancements to the remedy are not effectively reducing and controlling contamination at the site, then remedial objectives may be re-evaluated. As part of this evaluation, a Technical Impracticability (TI) Waiver may be sought by the Army. The TI Waiver would be granted by EPA if data demonstrate that available remedial technologies cannot attain the RAOs established in this ROD, based on the complexities of the contaminants and hydrogeology at Poleline Road.

8.0 STATUTORY DETERMINATIONS

The main responsibility of the Army, EPA, and ADEC under their legal CERCLA authority is to select remedial actions that are protective of human health and the environment. In addition, Section 121 of CERCLA, as amended by the Superfund Amendments and Reauthorization Act of 1986, provides several statutory requirements and preferences. The selected remedy must be cost-effective and utilize permanent treatment technologies or resource recovery technologies to the extent practicable. The statute also contains a preference for remedies that permanently or significantly reduce the volume, toxicity, or mobility of hazardous substances through treatment. CERCLA finally requires that the selected remedial action for each source area must comply with ARARs established under federal and state environmental laws, unless a waiver is granted.

8.1 PROTECTION OF HUMAN HEALTH AND THE ENVIRONMENT

The selected alternative for OU-B will provide long-term protection of human health and the environment and satisfy the requirements of Section 121 of CERCLA.

The selected remedy will provide long-term protection of human health and the environment by removing the contamination from soils and groundwater through installation of an HVE system. The remedy will eliminate the potential exposure routes and minimize the possibility of contamination migrating to drinking water sources. Groundwater monitoring/evaluation will be completed to assess contaminant plume movement and concentrations, and to ensure the effectiveness of the remedy.

Institutional controls will be in place to eliminate the threat of exposure to contaminated soils and groundwater until cleanup levels are achieved.

No unacceptable short-term risks will be caused by implementation of the remedy.

8.2 COMPLIANCE WITH APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS AND TO-BE-CONSIDERED GUIDANCE

The selected remedy for OU-B will comply with all ARARs of federal and state environmental and public health laws. These requirements include compliance with all the location-, chemical-, and action-specific ARARs listed below. No waiver of any ARAR is being sought or invoked for any component of the selected remedy.

8.2.1 Applicable or Relevant and Appropriate Requirements

An ARAR may be either applicable or relevant and appropriate. Applicable requirements are those substantive environmental protection standards, criteria, or limitations, promulgated under federal or state law, that specifically addresses a hazardous substance, remedial action, location, or other circumstance at a CERCLA site. Relevant and appropriate requirements are those substantive environmental protection requirements, promulgated under federal and state law, that, while not legally applicable to the circumstances at a CERCLA site, address situations sufficiently similar to those encountered at the CERCLA site so that the requirements' use is well-suited to the particular

Final

August 8, 1997

site. The three types of ARARs are described below:

- Chemical-specific ARARs usually are health- or risk-based numerical values or methodologies that establish an acceptable amount or concentration of a chemical in the ambient environment;
- Action-specific ARARs usually are technology- or activity-based requirements for remedial actions; and
- Location-specific ARARs are restrictions placed on the concentration of hazardous substances or the conduct of activity solely because the ARARs occur in special locations.

To-be-considered requirements (TBCs) are nonpromulgated federal or state standards or guidance documents that are to be used on an as-appropriate basis in developing cleanup standards. Because they are not promulgated or enforceable, TBCs do not have the same status as ARARs and are not considered required cleanup standards. They generally fall into three categories:

- Health effects information with a high degree of credibility;
- Technical information regarding how to perform or evaluate site investigations or response actions; and
- State or federal agency policy documents.

8.2.2 Chemical-Specific Requirements

- Federal Safe Drinking Water Act (40 Code of Federal Regulations [CFR] 141) and Alaska Drinking Water Regulations (18 Alaska Administrative Code [AAC] 80): The state and federal MCL and non-zero MCL goals were established under the Safe Drinking Water Act and are relevant and appropriate for groundwater that is a potential drinking water source. For the constituents of concern at OU-B, state and federal MCLs are equal; and
- AWQS (18 AAC 70): Alaska Water Quality Standards for Protection of Class (1)(A) Water Supply is applicable to the source area, and Class (1)(B) Water Recreation and Class (1) Aquatic Life and Wildlife (18 AAC 70) are applicable to surface water. Many of the constituents of groundwater regulated by AWQS are identical to state and federal MCLs.

8.2.3 Location-Specific Requirements

- Clean Water Act Section 404: Section 404 of the Clean Water Act,

Final

August 8, 1997

which is implemented by EPA and the Army through regulations found in 40 CFR 230 and 33 CFR 320 to 330, prohibits the discharge of dredged or fill materials into waters of the United States without a permit. This statute is relevant and appropriate to the protection of wetlands adjacent to Poleline Road;

- Army Regulation (AR) 200-2 (Environmental Quality), Environmental Effects of Army Actions: This regulation states Department of the Army policy, assigns responsibilities, and establishes procedures for the integration of environmental considerations into Army planning and decision making in accordance with 42 United States Code (USC) 4321 et seq., *National Environmental Policy Act of 1969*; the Council on Environmental Quality regulations of November 29, 1978; and Executive Order 12114, *Environmental Effects Abroad of Major Federal Actions*, January 4, 1979; and
- AR 210-20 (Master Planning for Army Installations): This regulation explains the concept of comprehensive planning and establishes policies, procedures, and responsibilities for implementing the Army Installation Master Planning Program. It also establishes the requirements and procedures for developing, submitting for approval, updating, and implementing the Installation Master Plan.

8.2.4 Action-Specific Requirements

- Federal Clean Air Act (42 USC 7401), as amended, is applicable for venting contaminated vapors;
- RCRA (42 USC 6939b[b]) states that contaminated groundwater cannot be injected unless: 1) being done as part of an action under Section 104 or 106 of CERCLA; 2) the contaminated groundwater is treated to "substantially reduce" hazardous constituents before reinjection; and 3) such response action will protect human health and the environment. The selected remedy employs extraction, treatment, and reinjection that substantially improve the condition of the aquifer and meet the substantive intent of this section of RCRA;
- The Safe Drinking Water Act, Underground Injection Control Program, (40 CFR 144) prohibits the movement of contaminated fluid into underground sources of drinking water. However, the act makes a provision for reinjection of treated groundwater into the same aquifer from which it was drawn pursuant to an action under CERCLA (40 CFR 144.13[c]);

Final

August 8, 1997

- RCRA (40 CFR 261, 262, 263, 264, and 268): Applicable for identifying, storing, treating, and disposing of hazardous waste;
- Alaska Wastewater Disposal Regulations (18 AAC 72). Section 72.600 addresses the requirements for engineering plans for treatment of wastewater (extracted groundwater), and Section 72.900 addresses permit requirements for operation of wastewater treatment systems; and
- Alaska Air Quality Control Regulations (18 AAC 50): Although on-site remedial actions do not require permitting, the substance portion of these regulations must be met for the venting of contaminated vapors associated with operation of the air stripping and SVE.

8.2.5 Information To-Be-Considered

The following information TBC will be used as a guideline when implementing the selected remedy:

- *State of Alaska Petroleum Cleanup Draft Guidance* will be used as a TBC for cleanup of petroleum contamination in soils.

8.3 COST EFFECTIVENESS

The selected remedy provides an overall effectiveness proportionate to its cost, such that it represents a reasonable value for the money spent.

8.4 UTILIZATION OF PERMANENT SOLUTIONS AND ALTERNATIVE TREATMENT TECHNOLOGIES OR RESOURCE RECOVERY TECHNOLOGIES TO THE MAXIMUM EXTENT PRACTICABLE

The Army, State of Alaska, and EPA have determined that the selected remedy represents the maximum extent to which permanent solutions and treatment technologies can be used in a cost-effective manner at OU-B. Of those alternatives that protect human health and the environment and comply with ARARs, the Army, State of Alaska, and EPA have determined that the selected remedy provides the best balance of trade-offs in terms of long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability; cost; and the statutory preference for treatment as a principal element in considering state and community acceptance.

The selected remedy would use readily available technologies and would be feasible to construct. The installation of HVE systems will be focused on the areas of highest soil contamination.

HVE in conjunction with air stripping provides a permanent solution by eliminating the source of contaminants and treating the off-site migration pathway.

Final

August 8, 1997

8.5 PREFERENCE FOR TREATMENT AS A MAIN ELEMENT

The selected remedy for OU-B satisfies the statutory preference for treatment of soil and groundwater by utilizing treatment as a main method to permanently reduce the toxicity, mobility, and volume of contaminated soil and groundwater.

Final

August 8, 1997

9.0 DOCUMENTATION OF SIGNIFICANT CHANGES

The selected remedy for OU-B is the same as the preferred alternative. No changes in the components of the preferred alternative have been made.

Final

August 8, 1997

APPENDIX B

RESPONSIVENESS SUMMARY

Final

August 8, 1997

**RESPONSIVENESS SUMMARY FOR THE RECORD OF DECISION FOR
REMEDIAL ACTION AT OPERABLE UNIT A AND OPERABLE UNIT B
FORT RICHARDSON, ALASKA**

OVERVIEW

U.S. Army Alaska (the Army), the United States Environmental Protection Agency (EPA), and the Alaska Department of Environmental Conservation (ADEC), collectively referred to as *the Agencies*, distributed a Proposed Plan for remedial action at Operable Unit A (OU-A) and OU-B, Fort Richardson, Alaska. OU-A comprises three source areas: the Roosevelt Road Transmitter Site Leachfield; Ruff Road Fire Training Area; and Building 986 Petroleum, Oil, and Lubricant Laboratory Dry Well. OU-B consists of one site: the Poleline Road Disposal Area (Poleline Road).

The Proposed Plan identified preferred remedial alternatives for Poleline Road, the only site in OU-B. The three source areas in OU-A were not considered for remedial action in the Proposed Plan. The Army, EPA, and ADEC have determined that the sites included within OU-A will be addressed under the conditions of the State-Fort Richardson Environmental Restoration Agreement (Two-Party Agreement) between the Army and ADEC.

The major components of the remedial alternative for Poleline Road are:

- High-vacuum extraction of the chlorinated-solvent-contaminated "hot spot";
- Sitewide institutional controls;
- Natural attenuation of contaminants; and
- Long-term groundwater monitoring.

Two formal comments regarding the Proposed Plan for the OU-B remedial action were received during the public comment period; these comments are summarized and presented in this Responsiveness Summary.

BACKGROUND OF COMMUNITY INVOLVEMENT

The public was encouraged to participate in the selection of the final remedies for OU-A and OU-B during a public comment period from January 20 to February 18, 1997. The *Fort Richardson Proposed Plan for Remedial Action at Operable Unit A and Operable Unit B* presents six options considered by the Agencies to address contamination in soil and groundwater at OU-B. The Proposed Plan was released to the public on January 18, 1997, and copies were sent to all known interested parties, including elected officials and concerned citizens. Informational Fact Sheets, prepared quarterly since June 1995, provided information about the Army's entire cleanup program at Fort Richardson and were mailed to the addresses on the same mailing list.

Final

August 8, 1997

The Proposed Plan summarizes available information regarding the OUs. Additional materials were placed into three information repositories: the University of Alaska Anchorage Consortium Library, Alaska Resources Library, and Fort Richardson Post Library. An Administrative Record, including all items placed in the information repositories and other documents used in the selection of the remedial actions, was established in Building 724 on Fort Richardson. The public was welcome to inspect materials available in the Administrative Record and the information repositories during business hours.

Interested citizens were invited to comment on the Proposed Plan and the remedy selection process by mailing comments to the Fort Richardson project manager; by calling a toll-free telephone number to record a comment; or by attending and commenting at a public meeting conducted on January 29, 1997, at the Russian Jack Chalet in Anchorage.

Basewide community relations activities conducted for Fort Richardson, which include OU-A and OU-B, have included:

- December 1994—Community interviews with local officials and interested parties;
- April 1995—Preparation of the Community Relations Plan;
- June 1995—Distribution of an informational Fact Sheet covering all OUs at Fort Richardson;
- June 29, 1995—An informational public meeting covering all OUs;
- October 1995—Distribution of an informational Fact Sheet covering all OUs at Fort Richardson;
- January 1996—Distribution of an informational Fact Sheet covering all OUs at Fort Richardson;
- March 1996—Establishment of information repositories at the University of Alaska Anchorage Consortium Library, Alaska Resources Library, and Fort Richardson Post Library, and the Administrative Record at Building 724 on Fort Richardson;
- March 14, 1996—An informational public meeting covering all OUs;
- April 1996—Distribution of an informational Fact Sheet covering all OUs at Fort Richardson;
- July 1996—Distribution of an informational Fact Sheet covering all OUs at Fort Richardson; and

Final

August 8, 1997

- October 1996—Distribution of an informational Fact Sheet covering all OUs at Fort Richardson.

Community relations activities specifically conducted for OU-A and OU-B included:

- January 17, 19, 22, 24, and 26, 1997—Display advertisement announcing the public comment period in the *Anchorage Daily News*;
- January 23, 1997—Display advertisement announcing the public comment period and public meeting in the *Alaska Star*;
- January 25, 26, 27, 28, and 29, 1997—Display advertisement announcing the public meeting in the *Anchorage Daily News*;
- January 20, 1997—Distribution of the Proposed Plan for final remedial action at OU-A and OU-B;
- January 20 to February 18, 1997—Thirty-day public comment period. No extension was requested;
- January 20 to February 18, 1997—Toll-free telephone number for citizens to provide comments during the public comment period. The toll-free telephone number was advertised in the Proposed Plan and the newspaper display advertisement that announced the public comment period; and
- January 29, 1997—Public meeting at the Russian Jack Chalet to provide information, a forum for questions and answers, and an opportunity for public comment regarding OU-A and OU-B.

SUMMARY OF COMMENTS RECEIVED DURING THE PUBLIC COMMENT PERIOD AND AGENCY RESPONSES

The public comment period on the Proposed Plan for remedial action at OU-A and OU-B was from January 20 to February 18, 1997. Two comments were received during the public comment period: one comment was mailed to the Army, and the second comment was recorded on the toll-free telephone line. These comments are summarized below.

1. **Public Comment:** A letter was received from a community member during the public comment period. The author indicates that after careful review of the Proposed Plan, he wants to be on the record as concurring with the Agencies' preferred alternative for OU-B.

Agency Response: The Agencies appreciate input from community members.

Final

August 8, 1997

2. **Public Comment:** The comment received on the toll-free telephone line acknowledged that the Proposed Plan was "nicely done" and that the presentation of the alternatives and discussion of the selection of the preferred alternative were "well supported, very well argued." However, the caller believes that although Alternative 6 will cost less than Alternative 4, Alternative 4 will "deal with the kind of contamination to the degree that it needs to be dealt with."

Agency Response: The Agencies appreciate input from community members. The National Oil and Hazardous Substances Pollution Contingency Plan Groundwater Protection Strategy requires that current and potential future use of groundwater be considered in remedy selection, and that groundwater resources be protected and restored if necessary and practicable. During a rigorous evaluation of remedial alternatives, the Agencies carefully weighed all of the factors that influence the selection of a preferred alternative. Cost effectiveness, risk to human health and the environment, and compliance with state and federal water quality statutes were the key considerations used to evaluate the six alternatives. At the conclusion of the evaluation process, Alternative 6 was determined to provide the most effective balance of the three criteria listed above. The preferred alternative will be implemented in a phased approach because of the complexity of the contaminant characteristics and the hydrogeology at the site. The actual length of time necessary to remediate the "hot spot" and the groundwater plume depends largely on the success of each phase. However, because there is no current or projected use of the groundwater anticipated during the period of remediation required for Alternative 6, the potentially shorter time frame required for remediation under Alternative 4 does not provide additional protection.

Mobilization & Demobilization	\$130,000	LS	1	\$130,000
Additional Monitoring Well Installation	\$40,000	well	2	\$80,000
Site Preparation (Clearing & Grubbing)	\$1,785	acre	1.4	\$2,499
B. Soil Vapor Extraction				
Extraction Well Installation (HDPE, 40' length)	\$3,000	well	10	\$30,000
Blower/Motor System (incl. knockout tank & instrumentation)	\$26,500	LS	1	\$26,500
Piping (4" HDPE)	\$13.65	lf	500	\$6,825
Insulation for Piping and Equipment	\$3,483	LS	1	\$3,483
Pump (from knockout tanks to discharge)	\$500	pump	3	\$1,500
HDPE Liner	\$4.05	sy	2,100	\$8,505
Vapor Extraction System Installation	\$8,706	LS	1	\$8,706
Electrical	\$3,483	LS	1	\$3,483
C. Groundwater Treatment				
Equalization Tank	\$12,200	tank	1	\$12,200
Piping (HDPE)	\$2.70	lf	1,400	\$3,780
Water Heating Units	\$2,524	each	1	\$2,524
Air Heating Units	\$8,506	each	1	\$8,506
Air Stripping Unit (incl. blower)	\$18,683	unit	1	\$18,683
Treatment Building	\$95	sf	200	\$19,000
Infiltration System (incl. piping, fittings, filters, emitters)	\$14,370	LS	1	\$14,370
Infiltration Piping Preparation (punch holes in pipes, install fittings,	\$3,593	LS	1	\$3,593
Infiltration Piping Bedding	\$21	cy	40	\$840
Infiltration Piping Installation	\$20	lf	500	\$10,000
TOTAL DIRECT COSTS (TDC)				\$394,996
CAPITAL INDIRECT COSTS				
A. Contractor's Overhead and Profit (50% TDC)				\$197,498
B. Engineering Design (25% TDC)				\$98,749
C. Design Studies (25% TDC)				\$98,749
D. Health and Safety (3% TDC)				\$11,850
TOTAL INDIRECT COSTS				\$406,846
TOTAL CAPITAL COSTS (Total Direct Costs + Total Indirect Costs)				\$801,841
II. ANNUAL O&M COSTS				
A. Treatment System O&M (years 1 to 5)				
Operations Labor (8 hr/wk @ 52 wks)	\$60	hr	416	\$24,960
Supervision Labor (8 hr/wk @ 52 wks)	\$100	hr	416	\$41,600
Electrical Power (SVE)	\$5,500	LS	1	\$5,500
Electrical Power (Treatment Building heating, lighting, etc.)	\$1,200	LS	1	\$1,200
Maintenance (8 hr/month @ 12 months)	\$100	hr	96	\$9,600
B. Treatment System O&M (years 6 to 30)				
Operations Labor (8 hr/month @ 12 months)	\$60	hr	96	\$5,760
Supervision Labor (8 hr/month @ 12 months)	\$100	hr	96	\$9,600
Electrical Power (SVE)	\$1,400	LS	1	\$1,400
Electrical Power (Treatment Building heating, lighting, etc.)	\$1,200	LS	1	\$1,200
Maintenance (8 hr/month @ 12 months)	\$100	hr	96	\$9,600
C. Groundwater Monitoring (30 years)				
Sampling Labor (40 hr/year)	\$60	hr	40	\$2,400
Sampling Analysis - VOCs (17 wells + 10% dupl)	\$180	sample	19	\$3,420
Sampling Analysis ⁽²⁾ (9 wells + 10% dupl)	\$360	sample	10	\$3,600
Sampling Analysis ⁽³⁾ (9 wells + 10% dupl)	\$145	sample	10	\$1,450
Supervision	\$100	hr	40	\$4,000
Data Evaluation and Reporting	\$85	hr	160	\$13,600
Supplies and Materials	\$600	ls	1	\$600

**ESTIMATED COSTS - ALTERNATIVE 6
SOIL VAPOR EXTRACTION OF "HOT SPOT"**

ITEM	UNIT COST	UNIT QUANTITY	COST
TOTAL O&M COSTS (30 years)			\$1,975,400
TOTAL CAPITAL AND O&M COSTS			\$2,777,241
CONTINGENCY (35% of Total Capital and O&M Costs)			\$972,034
SUBTOTAL (Total Capital and O&M Costs and Contingency)			\$3,749,276
USACE SIOH (8% Total Capital and O&M Costs and Contingency)			\$299,942
TOTAL ESTIMATED PROGRAM COSTS ⁽¹⁾			\$4,000,000

NOTES:

⁽¹⁾ Escalation costs are not included

⁽²⁾ Analysis for parameters which can indicate biodegradation of chlorinated solvents (e.g., NO₃-nitrogen, NO₂-nitrogen, NH₃-nitrogen, total Kjeldahl nitrogen, total phosphorus, SO₄, soluble iron, methane, ethane, ethene, sulfide, TOC, BOD)

⁽³⁾ Bacteria enumeration
