TCE	trichloroethene
URS	URS Corporation
VOCs	volatile organic compounds

SECTION ONE

Introduction

URS Corporation (URS), formerly URS Greiner Woodward-Clyde, was contracted by the United States Army Corps of Engineers on behalf of the United States Army, Public Works (Army) to conduct long-term groundwater monitoring at Operable Unit B (OUB), Poleline Road Disposal Area, Fort Richardson, Alaska. OUB is a former Army disposal area for chemical warfare training materials. OUB has been the subject of several environmental investigations, a feasibility study, and a treatability study.

Long-term groundwater monitoring has two objectives, 1) collect data on groundwater contaminant trends, and 2) devise an appropriate long-term site monitoring plan. According to the *Long-Term Groundwater Monitoring Work Plan, Operable Unit B, Poleline Road Disposal Area, Fort Richardson, Alaska* (WC 1997), eight rounds of sampling will be performed initially to evaluate groundwater contaminants over time. Seven rounds of sampling have been completed. The sampling dates were: November 1997, June 1998, October 1998, March 1999, October 1999, March 2000, and October 2000. This report summarizes the seventh round of sampling conducted in October 2000.

SECTION TWO

Scope of Work

Tasks to be completed under the *Long-Term Groundwater Monitoring Work Plan, Operable Unit B, Poleline Road Disposal Area, Fort Richardson, Alaska* (WC 1997) include the following:

- Conduct 8 rounds of groundwater sampling for volatile organic compounds (VOCs) in 20 monitoring wells at OUB, and sample for natural attenuation parameters during the first 2 rounds
- After each sampling round, prepare a technical memorandum that includes the results of the sampling event, a description of changes in contaminant concentrations since the previous sampling event, and recommendations for the next round of sampling
- Evaluate natural attenuation data after the first two rounds of sampling, and revise the sampling plan based on the evaluation

Evaluate data after the eight rounds of sampling are complete, and provide recommendations for future long-term monitoring needs.

3.1 LOCATION

The Fort Richardson Army Post occupies 61,500 acres of land (Figure 3-1). OUB is located on the Fort Richardson Army Post approximately 10 miles northeast of Anchorage, Alaska, 1 mile south of the Eagle River, and 0.6 miles north of the Anchorage Regional Landfill (Figure 3-2). Access to the area is by Poleline Road, a gravel road that runs northeast southwest along a powerline route and the Eklutna Water Line. OUB is bisected by Barrs Boulevard, a gravel road extending from the Glenn Highway to Poleline Road.

3.2 SITE DESCRIPTION

OUN is a low-lying, relatively flat area, bordered by a wooded, 80-foot hill to the west, wetlands directly south and southwest of the main disposal area (Area 3 and Area 4), and low, wooded hills on the remaining borders (Figure 3-3). The area where buried waste was detected by geophysical survey is approximately 1.5 acres. The main disposal area was cleared of vegetation during a 1994 removal action. No significant revegetation has occurred.

3.3 GEOLOGY

Regional surficial deposits are fluvially reworked glacial sediments and glacial tills. These deposits appear to be up to 30 feet thick at the site and consist of unstratified to poorly stratified clays, silts, sands, gravels, and boulders. A basal till lies below the surficial deposits and overlies an advance moraine/till complex. Underlying the glacial sediments is bedrock composed of hard, black fissile claystone.

The subsurface soils are dense glacial tills and generally silty sands with some gravel. Thin, discontinuous clay lenses were observed rarely. Observations during drilling confirm a typical fluvio-glacial setting; an heterogeneous system of discontinuous, relatively permeable channels with intervening denser, less permeable sediments.

3.4 HYDROGEOLOGY

Four water-bearing intervals have been identified at OUB, 1) a perched interval, 2) a shallow interval, 3) an intermediate interval, and 4) a deep aquifer. The detection of contaminants in all four intervals suggests that they are interconnected to some degree. Observations made while drilling indicate that the saturated intervals are separated by zones of very dense, low porosity, compact tills. The compact tills are dry or slightly moist.

The perched interval was observed in borings drilled between Area A-2 and the wetlands, and in Area A-3 (Figure 3-3). The top of the perched interval was encountered at 4 to 10 feet below ground surface (bgs), and the bottom was at 6 to 12 feet bgs. The average thickness of the perched interval is approximately 5 feet. The perched interval is recharged mainly by surface water from the wetlands, although some recharge also occurs from precipitation. The only monitoring well installed in the perched interval is MW-14 (AP-3746).

The shallow, saturated interval is an average of 10 feet thick; the top was encountered at 20 to 25 feet bgs, and the bottom was at 28 to 36 feet bgs. Groundwater elevations indicate that shallow groundwater is flowing in a north-northeast direction. Because of the localized nature of water-

bearing zones at this site, it is difficult to determine whether the water-bearing units are hydraulically connected between wells. The shallow interval is recharged by water from the discontinuous perched interval and by infiltration of precipitation.

The intermediate interval was observed while drilling monitoring well MW-16 (AP-3748). The saturated portion of the intermediate interval was encountered at approximately 65 to 95 feet bgs in MW-16 (AP-3748). The intermediate saturated interval does not correlate with the other deep wells on site, suggesting that it is an isolated lens with limited continuity. There may be several isolated lenses of saturated material within the intermediate interval.

Five monitoring wells at OUB penetrate the deep aquifer, the top of which was encountered from approximately 80 to 125 feet bgs. The deep aquifer is an advance moraine/till complex with thickness varying from 3 to 40 feet. Groundwater elevations indicate that the flow direction in the deep aquifer is locally to the northeast and regionally to the northwest. Available data indicate that the deep aquifer below the site is not connected with deep aquifers used for drinking water wells in the community of Eagle River (over 1 mile northeast).

The deep aquifer overlies a claystone bedrock unit with unknown thickness. Four of the five deep wells at OUB penetrate the bedrock unit, and the well screens extend slightly into the bedrock. The top of bedrock was encountered from 120 to 170 feet beneath the site.

The ultimate discharge area of the water-bearing intervals at OUB is probably the Eagle River, approximately 1 mile north of the site (Figure 3-2). The Eagle River flows into the Knik Arm of Cook Inlet approximately 5 miles northwest of OUB. The river is not used as a drinking water source.

3.5 LAND USE

The land surrounding OUB currently is used for Army training activities and recreational purposes. The Eklutna Water Line, a pipeline which supplies Anchorage and part of the Eagle River community with drinking water from Eklutna Lake (over 15 miles from the site), runs immediately west of the site.

At present, there are no plans for development of the OUB. Yield from the perched, shallow, and intermediate saturated intervals may be too low to supply an average household, and installation of septic systems would preclude use of the shallow or perched intervals for drinking water. The deep aquifer may provide sufficient yield for drinking water wells; however, future development of the deep aquifer for this purpose is unlikely, due to the proximity of the Eklutna Water Line.

3.6 HISTORY OF INVESTIGATION ACTIVITIES

Several investigations and a removal action have been conducted at OUB since its discovery in 1990. A brief summary of these activities is presented as follows:

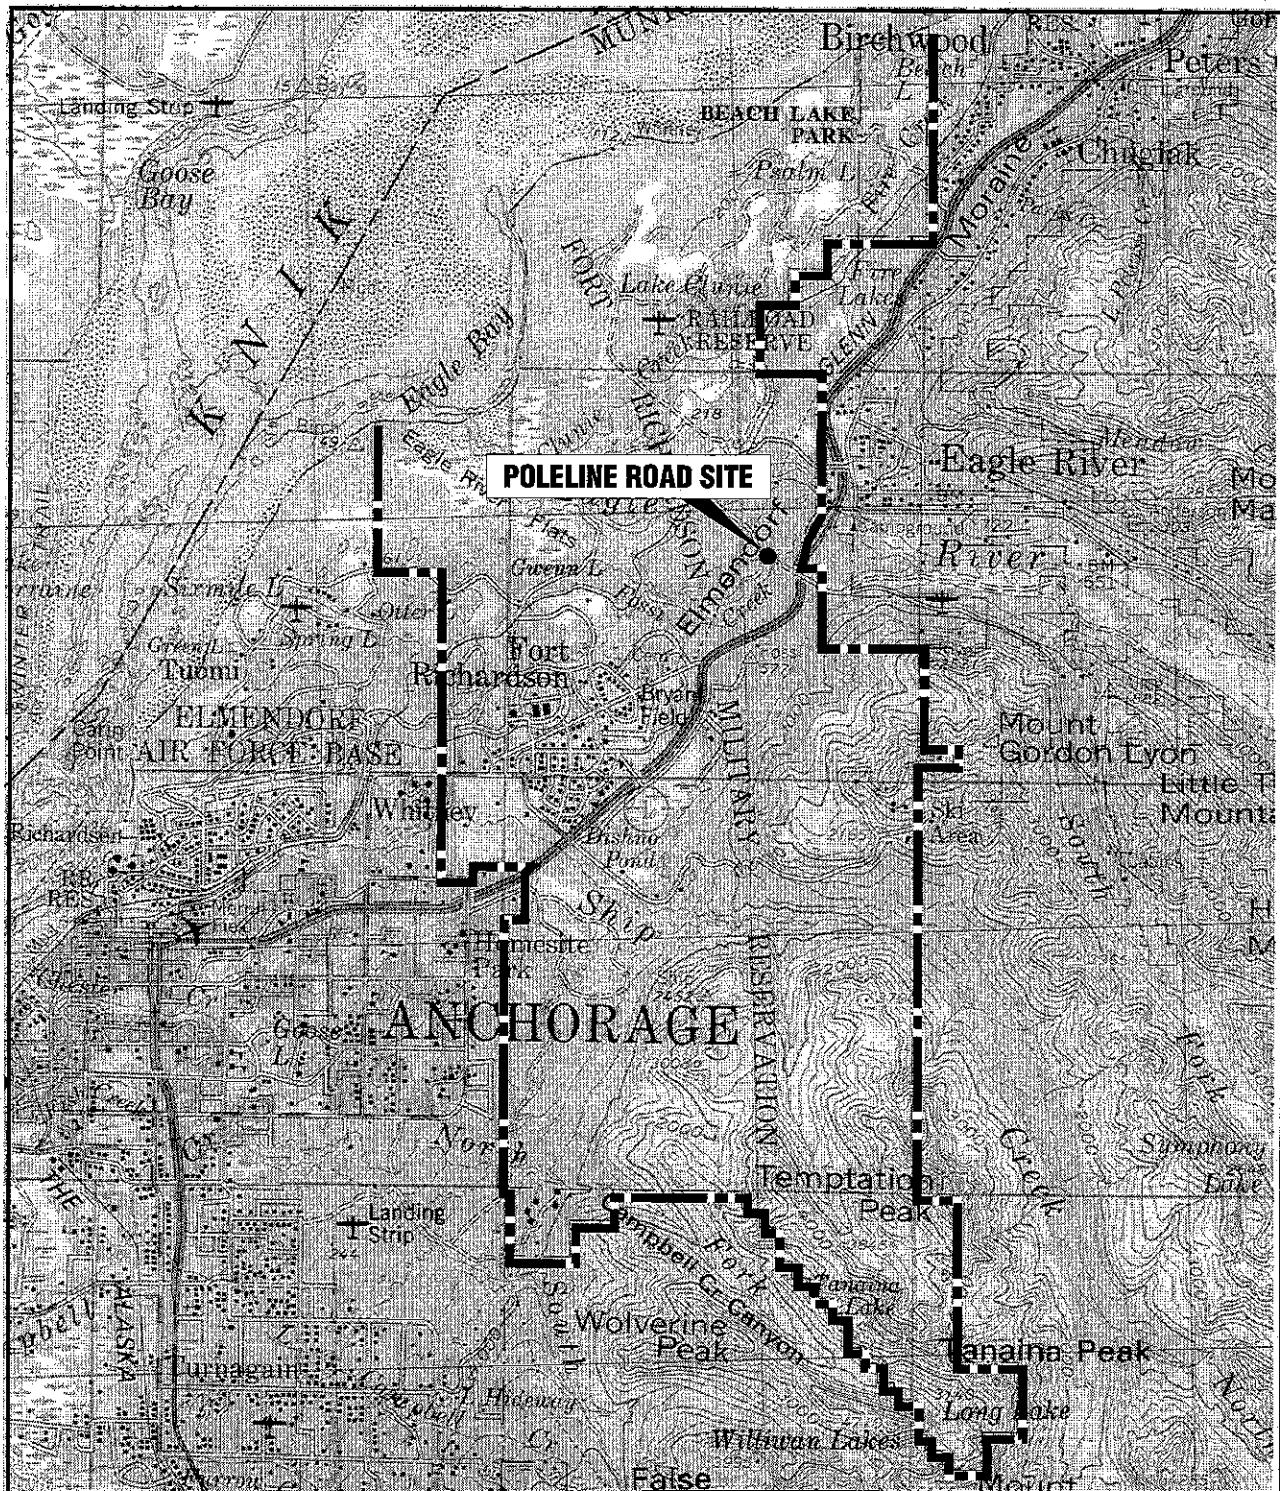

- In 1990 and in 1992, Environmental Science & Engineering, Inc. (ESE) conducted site investigations that included a geophysical survey, soil borings, a soil gas survey, monitoring well installation, groundwater sampling, a water level survey, and aquifer (slug) tests (ESE 1990, 1991, and 1993).

SECTION THREE

Environmental Setting

- In 1993, OHM conducted a rapid response removal action within areas A-3 and A-4 (OHM 1993).
- In 1994 and in 1995, the Cold Region Research and Engineering Laboratory (CRREL) conducted geophysical surveys (CRREL 1994, 1995).
- In 1995, URS (then Woodward-Clyde) performed a remedial investigation (RI) that consisted of surface and subsurface soil sampling, groundwater sampling, and installation of several new monitoring wells (URS 1995a).
- In 1995, URS conducted a human health risk assessment (HHRA) that included groundwater sampling and modeling (URS 1995b).
- In 1996, URS prepared a feasibility study (FS) to determine remedial alternatives (URS 1996).
- In 1996, URS performed an ecological risk assessment (ERA) in conjunction with an HHRA (URS 1997).
- In 1996, URS conducted a treatability study that provided data concerning soil vapor extraction (SVE) and air sparging. The study also included groundwater sampling and soil borings. (URS 1997).
- For several days in 1996, URS conducted a soil vapor extraction (SVE) evaluation study that included installing additional soil borings and soil/groundwater sampling (URS 1997).
- In 1997, URS conducted a design verification study to evaluate the applicability of six-phase heating (SPH) as an in situ technology for remediating solvent-contaminated soils. The study included soil borings and surface and subsurface soil sampling (URS 1998).
- In 1998, URS performed a dual-phased, high vacuum extraction (HVE) treatability study that included groundwater sampling, installing additional soil borings and monitoring wells, and subsurface sampling. (URS 1999).

Based on the success of SPH on soils, an additional design verification study was conducted in 1999. This recent design verification study evaluated the applicability of SPH as an in situ technology for remediating solvent-contaminated groundwater. New soil borings, surface and subsurface soil samples, and groundwater samples were collected (URS 2000).

Figure:

Monitoring wells selected for sampling during the initial eight rounds of the long-term groundwater monitoring program are shown on the site map (Figure 3-3). The rationale for sampling each well is presented in the *Long-Term Groundwater Monitoring Work Plan, Operable Unit B, Poleline Road Disposal Area, Fort Richardson, Alaska* (WC 1997). Standard operating procedures were used for sample collection, containerization, labeling, packaging, and sample transport. The procedures follow the guidelines established within the Groundwater Monitoring Plan (WC 1997).

Field tasks for the seventh round of groundwater monitoring included the following:

- Initial headspace readings of vapors in each monitoring well along with the measurement of static water levels
- Collecting field measurements for dissolved oxygen, pH, salinity, specific conductivity, temperature, and turbidity
- Purging and sampling up to 20 monitoring wells for VOCs

4.1 FIELD MEASUREMENTS

Initial headspace measurements for VOC were collected using a photoionization detector (PID) with an 11.7 lamp. Measurements of depth-to-water, pH, specific conductance, salinity, temperature, turbidity, and dissolved oxygen were recorded at each groundwater sampling location. Field measurements collected at each location are summarized in Table 4-1. Results of the field measurements are presented in Section 5 of this report.

4.2 GROUNDWATER SAMPLING

Groundwater samples were collected in accordance with procedures and protocols presented in Sections 4 through 7 of the *Long-Term Groundwater Monitoring Work Plan and Addendum No. 1*. Samples were collected using dedicated tubing and a submersible pump. Results of the laboratory analyses performed on groundwater are presented in Section 5 of this report. Laboratory reports are provided in Appendix A.

4.3 INVESTIGATION DERIVED WASTE

All investigation-derived waste (IDW) generated during the field investigation (e.g., equipment decontamination fluids, well purge water, and miscellaneous wastes) was containerized during sampling activities and transported to a U.S. Army Corps of Engineers designated treatment area. Handling and final disposal of all wastes were managed by the contractor under guidance from the Corps of Engineers.

4.4 DEVIATIONS FROM THE LONG-TERM GROUNDWATER MONITORING WORKPLAN

This section lists and describes conditions or actions that resulted in deviations from the work plan. In general, changes and problems encountered during sampling activities include insufficient groundwater for sampling, changes to sampling procedures due to field conditions, and damaged monitoring wells. The following deviations from the work plan occurred during this sampling event:

- No groundwater was encountered in monitoring well MW-14 (AP-3746). This monitoring well was also dry during the 1997, 1998, and 1999 sampling rounds.
- MW-4 (AP-4014) contained less water (0.25 feet) than was necessary to operate the submersible pump; therefore, it was not sampled.
- MW-17 (AP-3749) was not sampled because this monitoring well represents a background well, instead of a down-gradient well.

NOTES: MW-14 was dry in 1997, 1998, 1999, and 2000

-- = Not Sampled

Groundwater samples were collected from 18 of 22 groundwater wells at OUB between October 10 and 13, 2000. The depth to water was measured during well gauging (prior to purging each well for sampling) and was used with the elevation of the top of casing to calculate the water level elevation at each monitoring location. Two quality control duplicate samples, one matrix spike/matrix spike duplicate sample, and an equipment rinsate sample were collected. Tables 5-1 through 5-10 summarize the October 2000 results and provide historical analytical results for VOCs detected in OUB groundwater samples. Figure 5-1 is a graphical display of the chlorinated solvent degradation pathways.

Table 5-12 presents the VOCs that exceeded the maximum contaminant levels (MCLs). The MCL for trichloroethene (0.005 mg/l) was exceeded in 12 wells, with the concentrations ranging from 0.013 to 3.10 mg/l. The VOCs benzene, carbon tetrachloride, 1,1-dichloroethene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, PCE, 1,1,2-trichloroethene, and vinyl chloride also had concentrations that exceeded the MCLs in six wells. These wells represent a combination of shallow and deep aquifer samples covering most of the site area.

Several remedial activities, which may have impacted the concentration of contaminants in the groundwater, have occurred at the site. The most recent remedial effort was six-phase soil and groundwater heating in Area A-3. Concentrations of primary VOCs (1,1,2,2-tetrachloroethane, TCE, and PCE) were reduced in groundwater samples collected from several wells (MW-19, MW-23, MW-24, MW-21) as a result of the six-phase heating test conducted in the summer and fall of 1999. The impact of the 1999 test was limited to a small area (5,500 ft²). Because of the slow groundwater flow at the site (6.0×10^{-4} feet/day), it may take from several months to several years before lower concentrations of contaminants are observed in wells away from the test area.

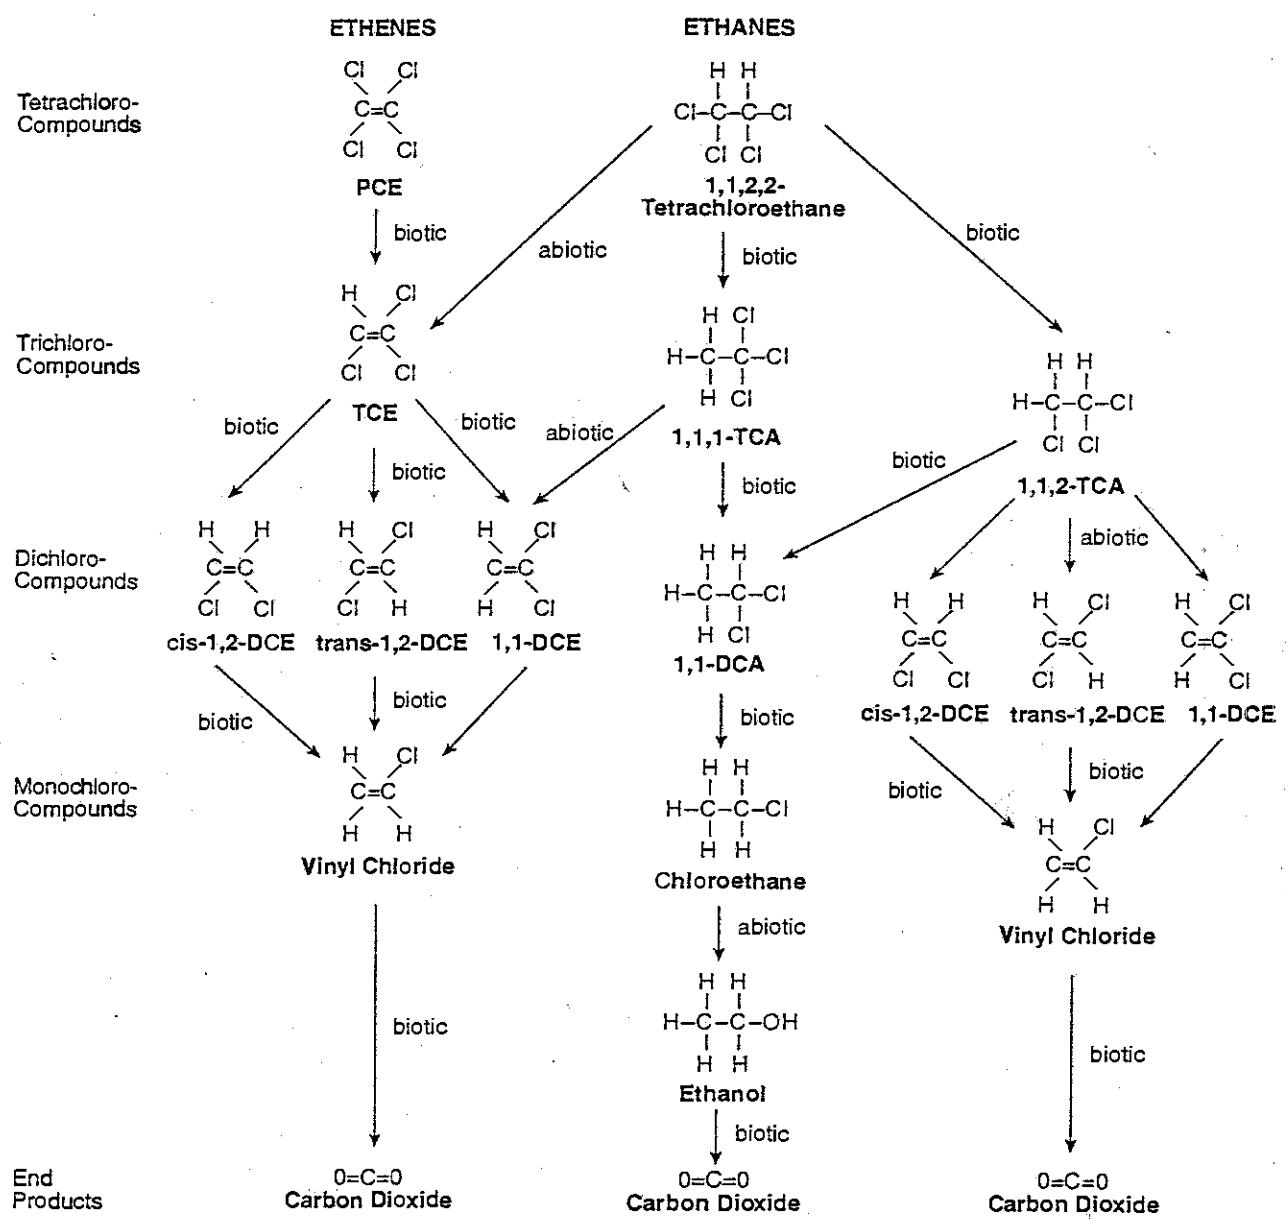

Isoconcentration maps for 1,1,2,2-tetrachloroethane, PCE, and TCE are presented in Figures 5-2, 5-3, and 5-4, respectively.

5.1 HEADSPACE MEASUREMENTS

Headspace measurements were recorded at 18 monitoring wells (Table 5-13). Measurements using an organic vapor monitor showed no volatile organic vapors in the headspace of 16 monitoring wells. The remaining 2 monitoring wells had headspace values of 2.6 and 117.5 parts per million (ppm).

5.2 GROUNDWATER ELEVATION

Table 5-14 summarizes OUB monitoring well water level measurements. The first groundwater samples were collected in November 1995 at the end of a wet summer and fall. Groundwater level measurements were collected every month starting November 1, 1995 and ending October 2, 1996. Water level measurements were also collected during each groundwater sampling round.

SECTION SIX

Conclusions

Nine rounds of groundwater data have been collected from October 1995 through October 2000. During this time, several remedial activities occurred at the site that may have impacted the concentration of contaminants in the groundwater (see Section 3.6). Variability in the concentration of contaminants from one round to the next has made it difficult to identify clear trends. However, in groundwater collected from several wells, the concentrations of primary VOCs (1,1,2,2-tetrachloroethane, TCE, and PCE) were reduced as a result of the 1999 Six-Phase Heating test. The impact of the 1999 test was limited to a small area (5,500 ft²). Because of the slow groundwater flow at the site, it may take from several months to several years for the concentration of contaminants in groundwater to be impacted at wells away from the test area. Three rounds of groundwater samples have been collected since the system was shut off in October 1999.

The concern has been raised that the solvents left in the soil, treated by SPH in 1999, may continue to impact the groundwater. The concentration of solvents that were observed in the groundwater samples collected for the October 2000 round generally were similar to the concentrations reported in the two previous sampling rounds. The concentration of 1,1,2,2-tetrachloroethane decreased significantly in MW-19 (from 0.04 mg/l to 0.0003 mg/l) and slightly in MW-22 (from 1.10 mg/l to 0.92 mg/l). Slight increases were observed in the concentration of 1,1,2,2-tetrachloroethane in MW-23 (from 0.32 mg/l to 0.42 mg/l) and MW-24 (0.14 mg/l to 0.23 mg/l). Wells MW-19, MW-22, MW-23, and MW-24 are located within or immediately adjacent to the area treated in 1999. The concentration of TCE was lower in the October 2000 samples collected from these wells compared those samples collected in March 2000. This data suggests that solvents remaining in the soil are not having a significant impact on groundwater concentrations.
